A Continuous Model of Matter based on AEONS

J. W. Vegt

Abstract
Within the domain of an electromagnetic model of matter it is supposed in this article that quantum mechanical probability waves are the observed relativistic effects of (auto-) confined electromagnetic waves. A relativistic coupling in the energy domain of the continuity equation results in the Schrödinger wave equation while an extended coupling including the momentum domain (observed as "spin") results in the Dirac equation. It is demonstrated in section 3 that the (relativistic) Dirac equation presumably originates from the Maxwell equations. Within the scope of this electromagnetic model of matter "light", or more generally "electromagnetic radiation", is regarded to be the building material of matter, which is effectively an inversion of the idea that light consists of elementary particles (photons). This postulated concept of inversion is extended to particles with a finite rest mass. The stability conditions for electromagnetic self confinements (EONS) are obtained by the gravitational or electro-magneto-static forces or a combination of them, controlling the confinement.

Key words: Auto confined electromagnetic entities, electromagnetic waves, probability waves, relativity, Schrödinger equation, Dirac equation, Phase-Locked Cavities

1. INTRODUCTION: ELECTROMAGNETIC ENTITIES
The acronym EON (Electromagnetic Entity) was first introduced by Wheeler in 1955 to introduce the concept of GEONS (Gravitational Electromagnetic Entities) which describe the auto confinements of electromagnetic radiation by self-generated gravity. AEONS (Auto Confined Electromagnetic Entities) describe in general the concept of auto confinements of electromagnetic radiation. AEONS include self-confined electromagnetic entities by gravity (GEONS) or by electro-magneto-static forces (EEONS - Electro-magneto-static Confined Electromagnetic Entities).

The most important developments in particle physics are based on a fundamental discontinuity in the composition of matter that is implied by each underlying particle model. This article describes an electromagnetically continuous model of matter that does not use the concept of elementary particles, but only of gravitationally or electro-magneto-statically self-confined electromagnetic radiation in a perfect vacuum. The model should be regarded as a component of a concept for what may prove to be an alternative approach in elementary particle physics.

2. AN ELECTROMAGNETIC (RELATIVISTIC) APPROACH OF THE SCHRODINGER WAVE EQUATION
An attempt is made to accommodate on physical grounds an intuitive awareness that the physical world is essentially a continuum. For the purposes of this model light, or rather electromagnetic radiation in the more general sense of the term, is regarded as the building material of matter, and of leptons in particular.

Rather than working with the electric field intensity $\vec{E}$ and the magnetic induction $\vec{B}$ directly, it is usually more convenient to work in terms of the potentials. The scalar potential $\phi$ and the vector potential $\vec{A}$ are defined by

$$\vec{E} = -\nabla \phi - \frac{\partial \vec{A}}{\partial t}$$

(1)

$$\vec{B} = \text{curl} \vec{A}$$

(2)

If the 4-potential is defined by:

$$\phi_a = \left( \frac{\phi}{c}, \vec{A} \right)$$

(3)

then the electromagnetic field tensor or the Maxwell tensor is defined by

$$F_{\alpha\beta} = \partial_a \phi_b - \partial_b \phi_a$$

(4)

in which $a,b$ assume the values 0,1,2,3 respectively where ict is the 0-component. Introducing the current density or source 4-vector $j_\alpha$ by

$$j_\alpha = \left( \frac{\partial \phi}{c}, \vec{j} \right)$$

(5)

the Maxwell equations in relativistic units ($c = 1$ and $G = 1$ is used in the equations 6, 7 and 8) can be written in the form

$$\partial_\alpha F_{\alpha\beta} = j_\beta$$

(6)
A continuous model of matter based on AEONS

\[ \partial_a F_{ab} + \partial_b F_{ab} + \partial_{[a} F_{b]} = 0 \quad (7) \]

The Maxwell energy-momentum tensor \( T_{ab} \) is

\[ T_{ab} = \frac{1}{2\pi} \left( e^{ab} F_{ac} F_{bd} + \frac{1}{4} \varepsilon_{abcd} F_{cd} F_{de} \right) \quad (8) \]

in source-free regions. In Euclidian space the metric tensor equals:

\[ \varepsilon_{ab} = \delta_{ab} \quad (9) \]

which means in general relativity the absence of a space-time curvature caused by mass. The equivalence of mass and energy in special relativity assumes all forms of energy will act as sources for the gravitational field, which is expressed by \( (10) \). The Einstein tensor \( \varepsilon_{ab} \) is supposed to be proportional to the Maxwell energy-momentum tensor

\[ \varepsilon_{ab} = \kappa T_{ab} \quad (10) \]

in which \( \kappa \) is a constant of proportionality, called the coupling constant and equal to

\[ \kappa = \frac{8\pi G}{c^2} \quad (11) \]

in which "G" is the gravitational constant. Substituting (8) in (10) results in the Einstein-Maxwell equations

\[ \varepsilon_{ab} = \frac{2\kappa}{c^2} \left( e^{ab} F_{ac} F_{bd} + \frac{1}{4} \varepsilon_{abcd} F_{cd} F_{de} \right) \quad (12) \]

Up to here the theory is classical and well known. An introduction of a new concept in electromagnetism is done by the introduction of the complex vector wave function denoted by \( \Phi(x,t) \) and the conjugated complex vector wave function \( \Phi^*(x,t) \), where:

\[ \Phi(x,t) = \sqrt{\frac{E}{2}} \left( \text{curl } \tilde{x}(x,t) - \frac{i}{c} \frac{\partial}{\partial t} \tilde{q}(x,t) + \frac{i}{c} \frac{\partial}{\partial t} \tilde{q}(x,t) \right) \quad (13) \]

In this equation, \( \varepsilon \) is the permittivity and \( c \) the speed of light, which equals \( (\varepsilon_\text{0})^{\text{c}^2} \). The complex vector functions are chosen such that the scalar product of both vector functions is equal to the relativistic electromagnetic mass density distribution \( \rho_{\text{EM}}(x,t) \) (which equals \( c^{-2} \) times the electromagnetic energy density) in the electromagnetic wave:

\[ \rho_{\text{EM}}(x,t) = \Phi(x,t) \cdot \Phi^*(x,t) \quad (14) \]

The transport of electromagnetic energy is determined by the Poynting vector \( \tilde{S}_{\text{EM}}(x,t) \), which equals the cross product of both vector functions multiplied by \( ic^2 \):

\[ \tilde{S}_{\text{EM}}(x,t) = ic^2 \left( \Phi^*(x,t) \times \Phi(x,t) \right) \quad (15) \]

In the absence of gravity the equations (14) and (15) equal the equations (3-A) and (4-A) in the appendix. If the model is to have plausible foundations, electromagnetic radiation must possess material properties. Free electromagnetic radiation in no way satisfies this condition. While obeying Maxwell's laws, it does not satisfy the Schrödinger wave equation or the laws of inertia. (Self-) confined electromagnetic radiation does however possess material properties.

Confined electromagnetic radiation exhibits the property of inertia\(^{19,28,29}\) which describes the measured electromagnetic mass of longitudinal photons. It further satisfies, in first-order approximation, the law of inertia\(^{26, p. 172}\) as formulated by Newton, subjected to the condition that the dimension of the self-confined radiation is much smaller than \( c^2 / a \), where \( a \) the modulus of acceleration of the wave packet, which is demonstrated in (78) and the equations (42-A) and (50-A) in the appendix, restricted to the absence of gravity. In order to simplify the calculation of the relativistic effects, the starting-point chosen for this model is a simplified model of external confinement consisting of perfectly reflecting mirrors (with adjustable curvature and negligible mass) within which a monochromatic beam of light is trapped, describing a Phase-Locked Cavity\(^{27,28,29}\). The mass of this confined electromagnetic wave is not negligible in this model. The monochromatic nature of the confined wave is essential to the entire model.

In a comparable way to free electromagnetic radiation, confined radiation satisfies the Lorentz transformation which describes the relativistic effects that arise if an observer moves at a relative velocity \( \nu \) with respect to the source of an electromagnetic wave, which is presented by:

\[ F_{ab} = L^a_b F_{cd} L^c_d \quad (16) \]

where \( a, b, c, d \) assume the values 0 to 3 respectively. \( L^a_b \) is the Lorentz transformation matrix, given e.g. in (57-A) for a transformation due to a relative velocity \( \nu \) along the \( x \)-axis between observer and field configuration and \( F_{ab} \) is the field describing matrix presented in (27-A). In classical quantum mechanics, which is mainly wave mechanics, it is sometimes preferable to consider confined electromagnetic radiation as the superposition of Fourier components propagating in the opposite direction. This is illustrated in equation (19-A) in the appendix. It will be clear that superposition of the Lorentz transformations of the Fourier components, propagating in opposite direction, has to be equal to the Lorentz transformation (56-A) in the appendix, which is the usual presentation. This equality is demonstrated e.g. by the Lorentz transformations (59-A) and (61-A) and (41), in which (41) is the result of the Lorentz transformation of the Fourier components, travelling in opposite directions.

In the most reduced example of plane monochromatic radiation, the confined radiation can be described by two plane waves travelling in opposite directions, confined by two perfect reflecting mirrors. When the movement is parallel to the confined beam, the observer simultaneously discerns an increased frequency of the beam propagating towards the observer and a decreased frequency of the beam propagating in the opposite direction\(^3,5,31\). The transformation of the beam propagating in the same direction of the observer is indicated as \( T^L \), while the transformation of the beam moving in the opposite direction is indicated by \( T^R \). The averaged observed
frequencies and energies of both beams, propagating in opposite directions, are increased according (10-A) and (11-A) in the appendix, by a factor $\sqrt{\frac{1+\frac{1}{2}\frac{v^2}{c^2}}{1}}$ in first order approximation and are proportional to the observed kinetic energy $\frac{1}{2}m_c^2v^2$ (where $m_c = W/c^2$) of the electromagnetic mass, which is accordingly classical mechanics. This is a characteristic of all kinds of confined radiation(27).

The Lorentz transformation of confined radiation is described by $E_x$ in which "s" differs in sign due to the described part of the confined wave. The corresponding tensor $T_{\alpha\beta}$ consists of a part $T_{\alpha\beta}^1$ describing the waves propagating in the same direction as the observer and a part $T_{\alpha\beta}^2$ describing the waves propagating in the opposite direction. The corresponding tensor $P_{\alpha\beta}$ transforms as follows:

$$P_{\alpha\beta} = L_{\alpha\beta}^1 T_{\alpha\beta}^1 T_{\alpha\beta}^2 + L_{\alpha\beta}^2 T_{\alpha\beta}^2 T_{\alpha\beta}^1$$

(17)

The Lorentz transformation(33)(17) is identical to (16) but offers some advantages.

A very simplified example of this concept is demonstrated in the appendix in the equations (9-A), (16-A) and (19-A). Making use of this basic principle, confined monochromatic radiation presents inertia (78) and obeys (20) Planck's law (21) for confined radiation with an arbitrary energy density, derived by integrating (20) over an arbitrary volume of (self-) confined radiation.

The Lorentz transformation of external radiation confinement within a system of perfectly reflecting mirrors, after which the aspect of (gravitational or electro-magneto-static) self-confinement is introduced at a later stage. The Schrödinger wave equation (56) is made under the assumption that the Lorentz transformation is valid in (slow) or non-accelerated movements. In that case one can consider a confined electromagnetic field, e.g. monochromatic radiation with frequency $f_0$ and energy $W_0$ confined between two perfect reflecting mirrors, which is compressed by moving one mirror slowly to the other in order that no kinetic energy of the confined electromagnetic mass is introduced.

Moving both mirrors towards each other with a constant velocity “v”, means that work has to be done to counterbalance the radiation pressure, given in (48-A) and (51-A), which equals $\frac{1}{2}w$ and in which $w$ is the energy density of the confined radiation, while simultaneously a rise in frequency occurs due to the Doppler shift. The distance between both mirrors is “l” and their surface “f”. The time $t$ equals $2l/c$ which again the reflected light requires to reach the moving reflecting mirror.

During the time $t$ work $W$ has done equal to:

$$\Delta W = \frac{1}{2}wA\Delta t = \frac{wA\Delta t}{c} = \frac{W_0}{c}$$

(18)

During the same interval $t$ the incident wave on the moving mirror is reflected with an increased frequency due to the Doppler shift, given by (10-A), and equals:

$$f' = f_0 + \Delta f = \gamma\left(1 + \frac{v}{c}\right)f_0$$

(19)

At low compression velocity (is nearly 1. Combining (18) and (19) results in:

$$\Delta W = \frac{W_0}{f_0} \Delta f$$

(20)

The term $f$ is the frequency shift after one complete reflection between both mirrors. Continuing the compression, the frequency shift also continues by discrete steps $f$ after each reflection of the moving mirror. This compression method has been applied in e.g. coupled high power pulse lasers in which light intensities of 100 [GW] in the U.V. region nowadays can be reached. There is no theoretical limit for a maximum frequency or energy density, only a practical one. Mirrors are not able to compress the confined radiation to frequencies comparable with frequencies corresponding to elementary particles and an energy density desired for self-confinement. Only in phenomena like black holes the desired compression forces may occur.

The constant $W_0 / f_0$ is indicated as $h_E$ and is comparable with Planck's constant. The ratio $W_0 / f_0$ is independent of the velocity “v” of the moving mirror, which implies that, independent of the velocity of compression, the frequency of confined radiation increases proportionally to the energy of the system. For a monochromatic system of confinement of radiation with homogeneous energy density, linear integration of (20) results in (21). Introducing a system of asymptotic infinite cubes with asymptotic infinite small sizes, all confining radiation of different energy density, leads to a more general law (21) for confined radiation with an arbitrary energy density, derived by integrating (20) over an arbitrary volume of (self-) confined radiation.

$$W = h_E f$$

(21)

where “W” is the total (self-) confined electromagnetic energy, and “f” is the frequency of the (self-) confined monochromatic wave(13).

In a system of self-confinement the corresponding frequency, wavelength and associated mass are determined by geometric conditions(52,53).

In circumstances of self-confinement, electromagnetic radiation satisfies the Schrödinger wave equation (56) when energy densities are sufficiently high(26) (of the order of $10^{23}$ [J/m^3]), demonstrated in (117). For this purpose, the starting point chosen is the model of external radiation confinement within a system of perfectly reflecting mirrors, after which the aspect of (gravitational or electromagnetic) self-confinement is introduced at a later stage. The mirror system has been chosen such that a vibration mode of electromagnetic radiation with frequency $f_0$ satisfies the consequent boundary conditions. In this example, if the system of mirrors is at rest with respect to an observer, an electric field vector is measured which equals to:

$$\vec{E}(x,t) = \frac{E_0}{\sqrt{2\pi}} \left(\delta(x) - \delta(x - L)\right) = -\frac{E_0}{4\sqrt{2\pi}} \int_0^L e^{-\frac{(x - \alpha)^2}{2\sigma^2}} e^{-\frac{(x - \alpha - L)^2}{2\sigma^2}} d\alpha$$

(22)

and in which $E_0$ is the amplitude of the electrical field intensity. The magnetic field vector observed is equal to:

$$\vec{B}(x,t)$$

(23)
where $\hat{e}_a$ is the unit vector in the direction of wave propagation and $\epsilon$ the permeability. The electric and magnetic field intensities (22) and (23) are measured by an observer at rest with respect to the system of mirrors. An observer, moving relative to the mirror’s coordinate system discerns a transformed electric and magnetic field intensity, frequency and wavelength. Introducing the 4-wave vector:

$$k_a = \begin{pmatrix} \frac{\omega_0}{c} \hat{e}_a \end{pmatrix}$$

(24)

the transformed frequency and wavelength(2) are presented by:

$$\omega'_a = \omega \frac{\bar{\gamma}}{\gamma} \quad \lambda'_a = \lambda \frac{\bar{\gamma}}{\gamma}$$

(25)

which 1-dimensional transformation is given in (12-A) and (13-A). Defining the Lorentz contraction term (2):

$$\gamma = \left( 1 - \frac{\hat{v}_a \cdot \hat{v}_a}{c^2} \right)^{-\frac{1}{2}}$$

(26)

in which $\hat{v}_a$ is the velocity of the observer relative to the coordinate system of the confining mirrors. Using (17), (22), (25) and (26), the transformed electric field intensity(2) is presented by:

$$E'_a(x',t') = \frac{\bar{\gamma}}{\gamma} E_{0} \sin(\omega_0 t) \sin(a) \times \frac{\hat{e}_a \times \hat{e}_a \times \hat{e}_0}{c}$$

(27)

The phase $\beta$ is given by:

$$\beta = \gamma \left( \omega_0 T_a' + \frac{(\hat{v}_a \cdot \hat{v}_a) \hat{e}_a \times \hat{e}_a}{c} \right)$$

(28)

where $T_a$ is the non-transformed frequency, mostly indicated as rest frequency. Phase $\alpha$ is given by:

$$\alpha = \gamma \left( \hat{e}_a \cdot \hat{e}_a' + \frac{(\hat{v}_a \cdot \hat{v}_a) \hat{e}_a \times \hat{e}_a}{c} \right)$$

(29)

This result is also demonstrated in a 1-dimensional example in the appendix in the equations (19-A) and (20-A). Phases $\beta$ and $\alpha$ in (28) and (29) are Lorentz invariant parameters, which follows from the reverse-transformation of the observer’s coordinates (G) to the confined wave packet's own system variables (G), presented in the 1-dimensional example in (25-A) and (26-A). The observer in (G) measures an electromagnetic wave with an apparent phase velocity, which is determined by (28):

$$v_p = \frac{\bar{\gamma}}{\gamma} c$$

(30)

which equation is comparable with (22-A) in the appendix. From (30) it follows that the phase velocity of a confined electromagnetic wave packet travelling at a velocity $\vec{v}_p$ with respect to an observer is always measured by the latter as greater than the velocity of light as a result of the relativistic transformations (17) and (25). This is accordingly the phase velocity of quantum mechanical probability waves describing elementary particles. Because the phase velocity is not related to the velocity of transport of information or energy and mass, (30) does not contradict the principle of relativity. Phase $\beta$ in (28) represents a relativistically transformed wavelength $\lambda'$ (in the direction of propagation of the wave packet) which is measured by a stationary observer in the coordinate system (G) with respect to which a confined electromagnetic monochromatic wave packet moves at a velocity $\vec{v}_p$, yielding:

$$\lambda' = \frac{2\pi \bar{\gamma}}{\bar{v}'_a}$$

(31)

Combining the Einstein relation $W_0 = m_0 c^2$, where $W_0$ is the rest energy and $m_0$ is the rest mass, with (21) and the fact that the modulus of the wave vector $\bar{E}$ is equal to $\omega_0 / c$, there follows from (31) a relation(19) for the observed relativistic 4-wavelength $\lambda_a$:

$$\lambda_a = \frac{\bar{\gamma}}{\gamma} c$$

(32)

which equation is equal to (24-A) for $a = 1$. In (32) $\lambda_a$ is the observed wavelength in coordinate direction $a$, the zero component $\lambda_0 = -\omega_0 c^2$ is the time component of the wavelength and $\hbar_0$ is the constant defined in (21). The term $\vec{p}_a$ is the relativistic momentum 4-vector of the confined electromagnetic monochromatic wave and is equal to the product of the relativistic mass $W_0 / c^2$ and the 4-vector velocity $(\vec{v}_p, \vec{v}_p)$. Relation (32) represents the observed relativistic effect of a confined electromagnetic monochromatic wave, derived from (17) and (25) and shows a characteristic correspondence to quantum mechanical probability waves, describing elementary particles.

The force, operating on confined electromagnetic radiation, can be derived from the tension tensor $\hat{T}$ which is a sub-tensor in (49-A), and the force equation (48-A). The momentum 4-vector is defined by:

$$\vec{p}_a = \left( \frac{\vec{E}_a \times \vec{B}_a}{c}, \vec{B}_a \right)$$

(33)

The transformed potential 4-vector is presented by:

$$\vec{\phi}'_a(x',t') = \frac{\bar{\gamma}}{\gamma} \vec{\phi}_a + \frac{\bar{\gamma}}{\gamma} \epsilon \frac{\partial \vec{E}_a}{\partial t'}$$

(34)

Using (3), (13) and (34), the transformed vector wave function $\vec{\psi}'(\vec{x}',t')$ is presented by:

$$\vec{\psi}'(\vec{x}',t') = \frac{1}{\sqrt{2}} \left( \begin{array}{c} \frac{\epsilon}{\sqrt{2}} \cos [\omega_0 (\vec{x}') \cdot \vec{s}] - \frac{\delta}{\sqrt{2}} \frac{\partial [\vec{E}_a \cdot (\vec{x}') \cdot \vec{s}]}{\partial t'} \\ \frac{\epsilon}{\sqrt{2}} \sin [\omega_0 (\vec{x}') \cdot \vec{s}] + \frac{\delta}{\sqrt{2}} \frac{\partial [\vec{E}_a \cdot (\vec{x}') \cdot \vec{s}]}{\partial t'} \end{array} \right)$$

(35)

Making use of (14) and (15), the pseudo Poynting 4-vector, which equals $\vec{E} \cdot \vec{B}$ (presented in the appendix in 51-A and related to the example in figure 1) is defined by:
The energy density $w_d$ describes the dynamic radiation part of the confined electromagnetic phenomena, excluding the mostly static energy part $w_s$ confining the system. The transformed Poynting 4-vector is presented by:

$$S' = \left[ \varepsilon (\mathbf{E} + w_s \mathbf{B}) \right] - \frac{1}{c^2} \left( \varepsilon_0 \mathbf{B} \times (\mathbf{E} + w_s \mathbf{B}) \right)$$  \hspace{1cm} (36)

Only under the condition that the energy density is built up of the dynamic part and the confining static part, the Poynting pseudo 4-vector in (37) transforms like a real 4-vector with Lorentz invariant modulus. Substituting (35) in (37), and using (34), this results in an alternative notation for the transformation of the Poynting 4-vector:

$$S' = \left\{ \varepsilon' \mathbf{E}' + w_s' \mathbf{B}' \right\} - \frac{1}{c^2} \left[ \varepsilon_0 \mathbf{B}' \times (\mathbf{E}' + w_s' \mathbf{B}') \right]$$ \hspace{1cm} (37)

The transformation (38) is for confined radiation in perfect balance identical to the transformation (56-A) for the index "d = 0" in the appendix. The momentum 4-vector of the confined radiation can be determined with the Poynting 4-vector (36) by (50-A), which equals:

$$p^\alpha = \frac{1}{c} \int \tau^\alpha \mathbf{V} \cdot d\mathbf{V} = \frac{1}{c^3} \int \mathbf{S}^\alpha \cdot d\mathbf{V}$$ \hspace{1cm} (39)

The momentum 4-vector for confined electromagnetic radiation is related by (39) to the Poynting 4-vector of the electromagnetic system. The introduction of a Poynting pseudo 4-vector for confined electromagnetic phenomena and its relation to the momentum 4-vector, given by (39), is an aspect in classical electromagnetism that relates in an important way classical mechanics to quantum mechanics. This relation is an elementary contribution to the particle-like property of confined radiation which implies that confined monochromatic radiation obeys the Schrödinger wave equation. It is important to realize that the confined dynamic field with frequency $\nu$ transforms differently from the static field describing the confining system itself due to the different orientation of the fields relative to the moving observer.

A dynamic Poynting pseudo 4-vector, describing the frequency-dependent part of the pseudo Poynting 4-vector, can be assigned to a monochromatic electromagnetic wave packet, externally confined in a system of mirrors and represented in its simplest form in (22) and (23). The transformation of the Poynting pseudo 4-vector can be performed more easily by using a notation reported earlier by Pauli(11), which split up the confined monochromatic wave in perfect symmetric parts related to the $L$ and $\bar{L}$ transformations. Using the Pauli notation and (38), the transformed Poynting 4-vector is represented by:

$$p'^\alpha = L_{\mathbf{p}}'^\alpha + \bar{L}_{\mathbf{p}}'^\alpha$$ \hspace{1cm} (40)

Equation (40) offers an important result. Electromagnetic Confinements in equilibrium or Electromagnetic Self-confinements appear to transform identically to elementary particles.
demonstrated in (59-A) and (61-A), in the appendix. The relativistic notation (41) for the Poynting 4-vector of a monochromatic electromagnetic wave packet leads to a relativistic equation, which demonstrates a remarkable correspondence with the Schrödinger, Klein/Gordon and Dirac equations. The derivation for the Klein/Gordon equation is essentially based on the equations (38) and (39), to which the wavelike nature is introduced later by applying (32). For this reason the Klein/Gordon equation also gives solutions for negative energy. The Dirac equation (102) corresponds with the Schrödinger wave equation at non-relativistic velocities(22). This is not in contradiction with the relativistic origin of (41) because it is a well known aspect that relativity is demonstrated most significant at non-relativistic velocities. For example the phenomenon of mass, which is a pure relativistic effect of energy, is demonstrated most significantly at rest on a scale or at non-relativistic velocities by its inertia. At relativistic velocities momentum and energy, or its equivalence mass, are less easier to separate. In this article the results of (41) are considered, restricted to electromagnetic confinements at non-relativistic velocities relative to the observer, and for that reason may only result in a Schrödinger-like wave equation.

The Schrödinger wave equation for (self-) confined electromagnetic radiation will be derived from the law of continuity below. The law of continuity for electromagnetic radiation, generally termed Poynting's theorem and given in the appendix (63-A), which describes the law of conservation of electromagnetic energy, is presented in the observer's system of coordinates in vacuum by:

$$\nabla \cdot \vec{S}(\vec{x}',t') = -\frac{\partial w(\vec{x}',t')}{\partial t'}$$  \hspace{1cm} (42)

In this equation $\vec{S}(\vec{x}',t')$ is Poynting's vector and $w(\vec{x}',t')$ the electromagnetic energy density observed in the coordinate system of the observer. In the case of non-relativistic velocities, substitution of (41) in (42) results in two equations in which the momentum and the energy, derived from the Poynting 4-vector, can be regarded as separate variables.

$$\nabla \cdot \left( \vec{S}_D \times \vec{S}_D \right) + \frac{v_D^2}{2c^2} \nabla \cdot \left( \vec{S}_D \times \vec{S}_D \right) = -\frac{1}{c^2} \frac{\partial \left( \vec{v}_D \cdot \vec{S}_D \right)}{\partial t'}$$  \hspace{1cm} (43)

$$\nabla \cdot \left( \vec{S}_D \times \vec{w}_D \right) = -\frac{1}{2} \frac{\partial \left( \vec{w}_D \cdot \vec{w}_D \right)}{\partial t'} - \frac{v_D \cdot \vec{j}_D}{2c^2} \frac{\partial \left( \vec{w}_D \cdot \vec{w}_D \right)}{\partial t'}$$  \hspace{1cm} (44)

In the case of non-relativistic velocities, equation (43) can be regarded as a momentum density equation and (44) as an energy density equation. In the case of relativistic velocities splitting (43) and (44) from (42) is only permitted under restricted conditions. At non-relativistic velocities under certain conditions, equation (44) changes into the conventional Schrödinger equation for (self-) confined electromagnetic radiation. Bosons, described by symmetric wave functions, as well as fermions, described by anti-symmetric wave functions, obey the Schrödinger wave equation. It is well known that electromagnetic phenomena can be described in terms of photons which belong to the boson group. A transition from bosons to fermions is not allowed in classical quantum mechanics. In a two particle problem bosons are described by a symmetric-wave function, in which the positions of the particles 1 and 2 are represented by the vectors $\vec{r}_1$ and $\vec{r}_2$ respectively:

$$\Psi(\vec{r}_1,\vec{r}_2) = \Psi(\vec{r}_2,\vec{r}_1)$$  \hspace{1cm} (45)

Fermions are described by an anti-symmetric wave function which is represented in a two particle problem as:

$$\Psi(\vec{r}_1,\vec{r}_2) = -\Psi(\vec{r}_2,\vec{r}_1)$$  \hspace{1cm} (46)

Because free electromagnetic waves are described by bosons, it would be a reasonable assumption that Electro-Magnetic (Self) confinements (EMS) behave like bosons. This contradicts however (44) which describes boson- as well as fermion-like behaviour. By exchanging two particles, described by EMS, the relative velocities between the observer and the particles may change in sign which is observed as a change in sign of the wave function, because the left of (44) only represents the relativistic part of the Poynting vector. The Lorentz matrices $\gamma^L$ and $\gamma^L$ exchange. By analogy with (13) the complex conjugated scalar functions $\Psi^*(\vec{x}',t')$ and $\Psi^*(\vec{x}',t')$ are introduced, yielding:

$$\bar{p}_{\text{EM}}(\vec{x}',t') = \Psi(\vec{x}',t') \Psi^*(\vec{x}',t')$$  \hspace{1cm} (47)

where $\bar{p}_{\text{EM}}(\vec{x}',t')$, just as in (14), is the averaged electromagnetic relativistic mass density. The function $\Psi(\vec{x}',t')$, by definition, is complex and satisfies:

$$\Psi(\vec{x}',t') = \frac{1}{2} \left( \bar{B}(\vec{x}',t') + \frac{\bar{E}(\vec{x}',t')}{c} \right)$$  \hspace{1cm} (48)

in which $\bar{B}(\vec{x}',t')$ and $\bar{E}(\vec{x}',t')$ are the effective values of the modulus...
of the magnetic induction and the electric field intensity, respectively, calculated across a microcube with the dimensions of half a wavelength. In the special case of the effective electric and magnetic field intensities calculated across a microcube, the position and time-dependence of the function $\Psi(\vec{x}', t')$ can be defined for a monochromatic electromagnetic wave packet with frequency $\nu_0$ with the aid of (22), (23), (27), (28) and (48) as follows:

$$\Psi(\vec{x}', t') = \Psi(\vec{x}', t') \cdot e^{i \vec{k} \cdot \vec{x}'}$$  \hspace{1cm} (49)

In (49) the function $\Psi(\vec{x}', t')$ is represented by the product of a real function, denoted by $\rho(\vec{x}', t')$, which is equal to the root of the electromagnetic mass density averaged across a microcube with the dimension of the wavelength $\lambda$, and the term $e^{i \vec{k} \cdot \vec{x}'}$ which, if the confined electromagnetic wave is at rest with respect to the observer, is only determined by the fundamental frequency $\nu_0$ of the confined wave. Subject to the condition of non-relativistic velocities and the assumption that the confined radiation energy density with frequency $\nu$ averaged across a microcube is equal to the static energy density of confinement, using the Einstein relation, averaged over a microcube, $\omega = \rho(E) c^2$ and substitution of (47) in (44) results in:

$$\Psi^* \nabla \cdot (\vec{V}_G \Psi) + (\vec{V}_G \Psi^*) \cdot \nabla \Psi^* = - \Psi \frac{\partial \Psi}{\partial t'} - \Psi \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (50)

For a confined monochromatic electromagnetic wave with a rest frequency $\nu_0$ travelling at a velocity $\vec{v}_G$ with respect to the observer and using (49) and (28) we have:

$$\nabla \Psi(\vec{x}', t') = e^{i \vec{k} \cdot \vec{x}'} \Psi(\vec{x}', t') + i \frac{\nu_0 \vec{v}_G}{c^2} \Psi(\vec{x}', t')$$ \hspace{1cm} (51)

Substitution of (51) in (50) results in:

$$\frac{c^2}{i \nu_0} \nabla^2 \Psi - \frac{c^4 e^{i \vec{k} \cdot \vec{x}'}}{c^2 \nu_0} \Psi - 2 i \frac{\nu_0}{c^2} \left(1 - \frac{\nu_0}{2c^2}\right) \Psi = -2 \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (52)

Using Einstein's relation $W = mc^2 = \hbar \nu_0$ with $\hbar = h / 2 \pi$, in which $h$ is introduced into equation (21) and $\nu_0$ is the frequency of the confined electromagnetic wave, (52) becomes:

$$\frac{\hbar^2}{2m_e} \nabla^2 \Psi + \frac{\hbar^2 e^{i \vec{k} \cdot \vec{x}'}}{2m_e} \Psi - mc^2 \left(1 + \frac{\nu_0}{2c^2}\right) \Psi = i \frac{\hbar}{\nu_0} \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (53)

Here $m_e$ is the relativistic mass of the confined electromagnetic energy and is equal to $(m_0, m_0)$, where $m_0$ is the rest mass of the confined electromagnetic field energy. The term $mc^2$ is the internal energy $V_0$ of the confined electromagnetic radiation. The change of the external potential energy $V_{PE}$ in an external force field is equal to the opposite change in the kinetic energy $V_{KE}$. Applying this in (53) results in:

$$\frac{\hbar^2}{2m_e} \nabla^2 \Psi + \frac{\hbar^2 e^{i \vec{k} \cdot \vec{x}'}}{2m_e} \Psi - V_0 \Psi + V_{PE} \Psi = i \frac{\hbar}{\nu_0} \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (54)

To reduce (54) to a Schrödinger-type wave equation, a self-confinement of the electromagnetic radiation is assumed in this model. This self-confinement can occur in several ways. A basic model assumes a self-confinement of electromagnetic radiation by gravitational waves generated by the electromagnetic energy itself(24).

In the case of a gravitational confinement (or an electro-magneto static confinement which has to fulfil the same conditions) it is assumed that, according to the basic principle of general relativity, any arbitrary energy "W" also represents a mass "m", which generates a gravitational field. In general relativity this effect is indicated by the coupling constant $\hbar$ in (11). Comparable with general relativity, a confined electromagnetic energy $W$ generates a gravitational field in a manner comparable to a material mass "m" = $W / c^2$. In the case of gravitational self-confinement (or electro-magneto static confinement), in this model the second term in (54) represents the internal potential energy $V_{PE}$ which occurs as a result of the interaction between gravitational confining forces and electromagnetic repulsive forces, given in (116). It follows from (116) that the second term in (54) vanishes at equilibrium. When the gravitational confining forces are in equilibrium with the repulsive electromagnetic radiation forces, the second term in (54) equals zero and (54) changes into:

$$- \frac{\hbar^2}{2m_e} \nabla^2 \Psi - V_0 \Psi + V_{PE} \Psi = i \frac{\hbar}{\nu_0} \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (55)

In the event of interaction with the surroundings the second term in (54) represents the internal potential energy $V_{PE}$ and (54) changes to:

$$- \frac{\hbar^2}{2m_e} \nabla^2 \Psi - V_0 \Psi + V_{PE} \Psi = i \frac{\hbar}{\nu_0} \frac{\partial \Psi}{\partial t'}$$ \hspace{1cm} (56)

Equation (56) demonstrates that at non-relativistic velocities, so that the energy and the momentum are observed as separated quantities, this equation is a special notation for (64-A) in the appendix in which circumstance the Schrödinger equation controls the energy domain.

### 3. THE DIRAC EQUATION RELATED TO THE MAXWELL EQUATIONS:

In what is undoubtedly one of the great papers in physics of this century, Dirac set up a relativistic wave equation which avoids the difficulties of negative probability density of the Klein-Gordon equation, and describes naturally the spin of the electron. Until Pauli and Weisskopf(23) reinterpreted the Klein-Gordon equation, it was believed that this Dirac equation was the only valid relativistic equation. It is now recognized that the Dirac equation and the Klein-Gordon equations are equally valid. The Dirac equation governs particles of spin $\frac{1}{2}$, the Klein-Gordon equation those of spin zero(22, p. 349). Self confined electromagnetic radiation (EMS) presents a characteristic effect indicated as "spin". Spin is a fundamental key in relativistic quantum mechanics(1,4,5,7,10). Dirac with his relativistic equation for the electron was the first to, as he put it, wed quantum mechanics and relativity together. The consequence of negative energies, that the Dirac equation presents when it is solved, introduces
the existence of anti-particles, necessary to wed quantum mechanics and relativity together\(^{(21)}\). This can be worked out for any "spin" as showed by Pauli and Weisskopf\(^{(23)}\). In this article, electromagnetic radiation is considered as the building material of a simultaneous particle/anti-particle combination\(^{(5)}\) which can under special conditions split up into two separate independent particles, both consisting of self confined electromagnetic radiation\(^{(14,49)}\). The Dirac equation\(^{(13,21)}\) can be derived from the continuity equation (42) or the Maxwell equation (60). The continuity equation equals:

\[ \nabla \cdot \mathbf{S}(x,t) = -\frac{\partial \mathbf{w}(x,t)}{\partial t} \]  
(57)

Substituting (14) and (15) in (57) results in:

\[ ic \, \nabla' \cdot (\Phi^* \times \Phi) = -\frac{\partial (\Phi \cdot \Phi^*)}{\partial t} \]  
(58)

Which can be written as:

\[ ic \, \Phi^* [\nabla' \times \Phi] - ic \, \Phi [\nabla' \times \Phi^*] = -\Phi \frac{\partial \Phi^*}{\partial t} - \Phi^* \frac{\partial \Phi}{\partial t} \]  
(59)

Equation (59) can be split up into two identical equations for \(\Phi\) and \(\Phi^*\) respectively, which only are distinguished in sign:

\[ \frac{\partial \Phi}{\partial t} = -\frac{i}{c} \frac{\partial \Phi^*}{\partial t} \]  
(60)

Substituting equation (3-A) in the appendix in (60) demonstrates that the Maxwell equations (29-A) and (32-A) follow straight from the continuity equation (57)\(^{(23,p.201)}\). To transform the electromagnetic vector wave function \(\Phi\) into a scalar (spinor or 1-dimensional matrix) representation, the Pauli spin matrices are introduced:

\[
\begin{align*}
\sigma_x &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \\
\sigma_y &= \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \\
\sigma_z &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}
\end{align*}
\]  
(61)

which matrices are presented by the vector notation \(\mathbf{\sigma}\). The Pauli spin matrices obey the equation:

\[ \sigma_a \sigma_b = i \epsilon_{abc} \sigma_c + \delta_{ab} \]  
(62)

in which \(\epsilon_{abc}\) is the Levi-Civita tensor whose value is +1 or -1 if \(abc\) is an even or odd permutation respectively. The electromagnetic vector wave function \(\Phi\) is transformed into the matrix representation \(\mathbf{U}\) by the scalar product of the Pauli matrices \(\mathbf{\sigma}\) and the vector wave function \(\Phi\) :

\[ \mathbf{U} = \mathbf{\sigma} \cdot \Phi = \begin{pmatrix} \Phi_x \\ \Phi_y \\ \Phi_z \end{pmatrix} = \begin{pmatrix} u_3 & u_1 \\ u_1 & u_4 \\ u_4 & u_3 \end{pmatrix} \]  
(63)

For a more common notation in the continuity equation the spinor \(\mathbf{U}\) is presented as:

\[ \mathbf{\sigma} \cdot \mathbf{U} = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{pmatrix} = \begin{pmatrix} \Phi_x - i \Phi_y \\ \Phi_x + i \Phi_y \\ -\Phi_z \\ \Phi_z \end{pmatrix} \]  
(64)

Both sides of equation (60) are multiplied scalar by the Pauli spin matrices:

\[ \mathbf{\sigma} \cdot \left( \nabla' \times \Phi \right) = -\frac{i}{c} \mathbf{\sigma} \cdot \left( \frac{\partial \Phi}{\partial t} \right) \]  
(65)

From equation (62) it follows that:

\[ (\mathbf{\sigma} \cdot \nabla) (\mathbf{\sigma} \cdot \Phi) = \delta_{ab} (\nabla \cdot \Phi) + i \mathbf{\sigma} \cdot (\nabla \times \Phi) \]  
(66)

Substituting (66) in (65) results in:

\[ (\mathbf{\sigma} \cdot \nabla) (\mathbf{\sigma} \cdot \Phi) = \frac{\partial}{\partial t} \left( \frac{\partial \Phi}{\partial t} \right) \]  
(67)

From (61), (63) and (67) follows the equation:

\[ (\mathbf{\sigma} \cdot \nabla) \mathbf{U} = \begin{pmatrix} \frac{\partial}{\partial y} - \frac{i}{c} \frac{\partial}{\partial z} \\ \frac{\partial}{\partial x} - \frac{i}{c} \frac{\partial}{\partial z} \\ \frac{\partial}{\partial x} + \frac{i}{c} \frac{\partial}{\partial y} \end{pmatrix} \begin{pmatrix} u_3 & u_1 \\ u_1 & u_4 \\ u_4 & u_3 \end{pmatrix} = \begin{pmatrix} y_3 \\ y_4 \end{pmatrix} \]  
(68)

in which:

\[ y_3 = \frac{\partial u_4}{\partial x} - i \frac{\partial u_3}{\partial y} + \frac{\partial u_1}{\partial z} \]  
\[ y_4 = \frac{\partial u_1}{\partial x} + i \frac{\partial u_2}{\partial y} - \frac{\partial u_3}{\partial z} \]  
\[ y_1 = \frac{\partial u_3}{\partial x} - i \frac{\partial u_4}{\partial y} + \frac{\partial u_1}{\partial z} \]  
\[ y_2 = \frac{\partial u_2}{\partial x} + i \frac{\partial u_1}{\partial y} - \frac{\partial u_3}{\partial z} \]  
(69)

Substituting (68) and (69) in (67) results in a matrix presentation for the Maxwell equations (29-A) and (32-A):

\[ \frac{\partial \mathbf{u}_4}{\partial x} - i \frac{\partial \mathbf{u}_3}{\partial y} + \frac{\partial \mathbf{u}_1}{\partial z} - \nabla \cdot \Phi = \frac{1}{c} \frac{\partial \mathbf{u}_4}{\partial t} \]  
(1)
\[ \frac{\partial \mathbf{u}_1}{\partial x} + i \frac{\partial \mathbf{u}_2}{\partial y} - \frac{\partial \mathbf{u}_3}{\partial z} = \frac{1}{c} \frac{\partial \mathbf{u}_1}{\partial t} \]  
(2)
\[ \frac{\partial \mathbf{u}_3}{\partial x} - i \frac{\partial \mathbf{u}_4}{\partial y} + \frac{\partial \mathbf{u}_1}{\partial z} = \frac{1}{c} \frac{\partial \mathbf{u}_3}{\partial t} \]  
(3)
\[ \frac{\partial \mathbf{u}_2}{\partial x} + i \frac{\partial \mathbf{u}_1}{\partial y} - \frac{\partial \mathbf{u}_3}{\partial z} = \frac{1}{c} \frac{\partial \mathbf{u}_2}{\partial t} \]  
(4)

The Maxwell equations (70) demonstrate an asymmetry in relation to the spatial charge density which is countered by adding and
subtracting the equations (70-1), (70-3) and (70-2), (70-4) respectively.

\[
\begin{align*}
\frac{\partial (u_x + u_y)}{\partial x} &= -i \frac{\partial (u_x + u_y)}{\partial y} + \frac{\partial (u_x + u_y)}{\partial z} - \nabla \cdot \mathbf{F} = \frac{\partial (u_x + u_y)}{\partial t} \\
\frac{\partial (u_x - u_y)}{\partial x} &= i \frac{\partial (u_x - u_y)}{\partial y} - \frac{\partial (u_x - u_y)}{\partial z} - \nabla \cdot \mathbf{F} = \frac{\partial (u_x - u_y)}{\partial t} \\
\frac{\partial (u_x - u_y)}{\partial x} &= -i \frac{\partial (u_x - u_y)}{\partial y} + \frac{\partial (u_x - u_y)}{\partial z} + \nabla \cdot \mathbf{F} = \frac{\partial (u_x - u_y)}{\partial t}
\end{align*}
\] (71)

In a charge-free region it follows from (3-A), (30-A) and (31-A) that \( \mathbf{F}(\vec{x}, t) \) is divergence-free and the matrix presentation (71) for the Maxwell equations equal the Dirac equation for elementary particles (e.g. photons) with rest mass which equals zero\(^{(22, p.351, p.379)}\).

In a charge-free region, \( \nabla \cdot \mathbf{F} = 0 \) and the Maxwell equations (71) can be rewritten as:

\[
\begin{align*}
\frac{\partial (u_x + u_y)}{\partial x} &= -i \frac{\partial (u_x + u_y)}{\partial y} + \frac{\partial (u_x + u_y)}{\partial z} - \nabla \cdot \mathbf{F} = \frac{\partial (u_x + u_y)}{\partial t} \\
\frac{\partial (u_x + u_y)}{\partial x} &= i \frac{\partial (u_x + u_y)}{\partial y} - \frac{\partial (u_x + u_y)}{\partial z} - \nabla \cdot \mathbf{F} = \frac{\partial (u_x + u_y)}{\partial t} \\
\frac{\partial (u_x - u_y)}{\partial x} &= -i \frac{\partial (u_x - u_y)}{\partial y} + \frac{\partial (u_x - u_y)}{\partial z} + \nabla \cdot \mathbf{F} = \frac{\partial (u_x - u_y)}{\partial t}
\end{align*}
\] (72)

The corresponding spinor \( \vec{U}_C \) is given by (64):

\[
\vec{U}_C = \begin{pmatrix}
  u_x + u_x \\
  u_x + u_y \\
  u_x - u_y \\
  u_x - u_y
\end{pmatrix} = \begin{pmatrix}
  \Phi_x - i \Phi_y + \Phi_z \\
  \Phi_x + i \Phi_y - \Phi_z \\
  \Phi_x - i \Phi_y - \Phi_z \\
  \Phi_x + i \Phi_y + \Phi_z
\end{pmatrix}
\] (73)

Because mass is a relativistic effect of (confined) energy, it is a reasonable suggestion to couple the coordinate system of the electromagnetic energy confinement relativistically to the coordinate system of the observer to introduce the relativistic effects of confined energy, observed as a finite rest mass, into the continuity equation (57) or its equivalent, the Maxwell equations (72). It is taken into account that the Maxwell equations (72) describe in principle particles with a rest mass zero (e.g. photons). To derive from (72) the Dirac equation, describing elementary particles with a finite rest mass, a simultaneous particle/anti-particle combination is chosen which particle pair has to satisfy the Maxwell equations (72). This was done before by the relativistic derivation of the Schrödinger equation (56) from the continuity equation (42) and in a comparable way in the following by the derivation of Newton’s law (111) from the relativistic radiation pressure derived from (108). This will be realised by defining the relativistic vector wave function \( \vec{F}(\vec{x}, t) \) in (13), describing the electromagnetic field configuration, which is split up into two parts:

\[
\vec{F} = \vec{F}_1 + \vec{F}_2
\] (74)

Equation (74) applies to a monochromatic electromagnetic wave with frequency \( T_0 \) which is observed by an observer with a relative velocity \( v \) with respect to the confined electromagnetic wave. In this relation the function \( \vec{F}_1 \) consists of an elementary function \( \vec{F}_1 \), a relativistic function \( \vec{F}_2 \) which describes the transformed relativistic part. For the elementary function \( \vec{F}_1 \) we have the relation:

\[
\vec{F}_1 = \frac{\gamma \Phi_E}{8c} \begin{pmatrix}
  e^{i \alpha} + e^{-i \alpha} \\
  e^{i \beta} + e^{-i \beta}
\end{pmatrix} \vec{e}_H
\] (75)

\[
+ \frac{i \gamma \Phi_E}{8c} \begin{pmatrix}
  e^{i \alpha} - e^{-i \alpha} \\
  e^{i \beta} - e^{-i \beta}
\end{pmatrix} \vec{e}_E
\] (76)

Assuming a monochromatic electromagnetic wave packet with rest frequency \( T_0 \), for the electric field intensity \( \vec{E}(\vec{x'}, \vec{t'}) \) according to (22) in the coordinate system of an observer moving at a relative velocity \( \vec{v} \) with respect to the confined wave, the following relation applies:

\[
\vec{E}(\vec{x'}, \vec{t'}) = \frac{\gamma c \Phi_E}{\sqrt{2 \epsilon}} \begin{pmatrix}
  \vec{e}_G \times \vec{e}_H \\
  \vec{v} \times \vec{e}_E \cos(\alpha) \cos(\beta)
\end{pmatrix}
\] (77)

for the observed electric field intensity and according to (23):

\[
\vec{H}(\vec{x'}, \vec{t'}) = \frac{\gamma \Phi_E}{\mu \sqrt{2 \epsilon}} \begin{pmatrix}
  \vec{e}_H \cos(\alpha) \cos(\beta) - \vec{v} \times \vec{e}_E / c \sin(\alpha) \sin(\beta)
\end{pmatrix}
\] (78)

for the observed magnetic field intensity. When the observer is at rest, relative to the electromagnetic field confinement (77) reduces, using (28) and (29), to:

\[
\vec{E}(\vec{x}, \vec{t}) = \frac{c \Phi_E}{\sqrt{2 \epsilon}} \sin(k \cdot \vec{x}) \sin(\omega_d \vec{t}) \vec{e}_G
\] (79)

and a magnetic field intensity is observed equal to:

\[
\vec{H}(\vec{x}, \vec{t}) = \frac{\Phi_E}{\mu \sqrt{2 \epsilon}} \cos(k \cdot \vec{x}) \cos(\omega_d \vec{t}) \vec{e}_H
\] (80)
To split up the spinor \((73)\) into two parts, describing the part \(+i\hat{T}\) and \(-i\hat{T}\) respectively, equation \((74)\) is rewritten into:

\[
\Phi = \Phi_A + \Phi_B
\]

(81)

In which the vector wave function \(\Phi_A\) yields the relation:

\[
\Phi_A = \frac{\gamma \Phi_R}{4} \left( 1 + \frac{\vec{V}_C}{c} \times \vec{\epsilon}_x \right) \cos(\alpha)\vec{e}_y + \sin(\alpha)\vec{e}_x e^{i\beta} = \Phi_{RAE} e^{i\beta}
\]

(82)

and the vector wave function \(\Phi_B\) yields:

\[
\Phi_B = \frac{\gamma \Phi_R}{4} \left( 1 + \frac{\vec{V}_C}{c} \times \vec{\epsilon}_x \right) \cos(\alpha)\vec{e}_y - \sin(\alpha)\vec{e}_x e^{-i\beta} = \Phi_{RAE} e^{-i\beta}
\]

(83)

where \(\Phi_{RAE}\) and \(\Phi_{RAE}\) are real vector functions for the terms \(e^{i\alpha}\) and \(e^{-i\alpha}\). From (82) and (83) it follows that the complex vector wave function \(\Phi\) can be divided into terms of \(e^{i\alpha}\) and \(e^{-i\alpha}\) which has already been reported by Pauli(11). For the electromagnetic mass distribution of a monochromatic (self)-confined electromagnetic wave it follows from (14) and (81) that:

\[
\rho_{RA}(x,t) = \langle \Phi_A + \Phi_B | \Phi_A^* + \Phi_B^* \rangle
\]

(84)

An "x-y-z" coordinate system is introduced, which is rotated in such a way that the velocity \(\vec{V}_C\) of the observer relative to the confinement is along the z-axis. A linear superposition of confined waves propagating along the z-axis is considered, describing a monochromatic electromagnetic wave-packet. A monochromatic wave packet around frequency \(\hat{T}\) is considered, which is determined by:

\[
\Phi(z', t') = \int \frac{d^4k}{2\pi^3} \Phi(k', \omega) e^{ik'z'} e^{i\omega t'} \theta_{\Delta k} \theta_{\Delta \omega}
\]

(85)

in which \(\Phi(k', \omega)\) presents the scalar components in (82) and (83) and \(\Delta \omega / \omega < 1\) as well as \(\Delta k / k < 1\). The vector function \(\Phi(z, t)\) represents the part of the vector wave function describing waves propagating only in the z-direction. From (82) and (83) it follows for the x and y components, under the restriction that the electric field intensity is oriented along the x-axis:

\[
\Phi_{\text{RAE}} = \frac{\gamma \Phi_R}{4} \left( 1 + \frac{\vec{V}_C}{c} \times \vec{\epsilon}_x \right) \cos(\alpha)\vec{e}_y + \sin(\alpha)\vec{e}_x e^{i\beta} = \Phi_{RAE} e^{i\beta}
\]

(86)

\[
\Phi_{\text{RAE}} = \frac{\gamma \Phi_R}{4} \left( 1 + \frac{\vec{V}_C}{c} \times \vec{\epsilon}_x \right) \cos(\alpha)\vec{e}_y - \sin(\alpha)\vec{e}_x e^{-i\beta} = \Phi_{RAE} e^{-i\beta}
\]

The vector wave function, describing the confined electromagnetic wave packet equals:

\[
\Phi(z', t') = \Phi_{RAE} e^{i\beta} + \Phi_{RAE} e^{-i\beta}
\]

(87)

The observer is moving in positive direction along the z-axis. The coordinate system is oriented in such a way that yields: \(\hat{e}_x \times \hat{e}_y = \hat{e}_z\). This results in a relation for the relativistic terms in (82) and (83) which equals: \(\vec{V}_C \times \vec{\epsilon}_y = -\nu \hat{e}_z\) and \(\vec{V}_C \times \vec{\epsilon}_z = \nu \hat{e}_y\). Substituting (82) and (83) in (87) and using (73) and (3-A) results in:

\[
\Phi_{RAE} = \frac{\gamma \Phi_R}{4} \left( -i \left( 1 + \frac{\nu}{c} \right) e^{\beta} - i \left( 1 - \frac{\nu}{c} \right) e^{-\beta} \right)
\]

(88)

(89)

Because new spinor components are created which essentially differ from the original spinor components in (64), these components are indicated by \(\hat{\epsilon}\). Combining (73) and (88) defines the way to split up both spinors.

\[
\Phi_{RAE} = \frac{\gamma \Phi_R}{4} \left( u_1 + u_3 \right) + \frac{\gamma \Phi_R}{4} \left( u_2 + u_4 \right)
\]

(90)

The spinor (90) is split up into two parts, describing respectively a particle/anti-particle presentation which results into:

\[
\Phi_{RAE} = \frac{\gamma \Phi_R}{4} \left( -i \left( 1 + \frac{\nu}{c} \right) e^{\beta} - i \left( 1 - \frac{\nu}{c} \right) e^{-\beta} \right)
\]

(91)
symmetric in the arguments $\gamma$ and $\delta$, presented by 28 and 29), the Maxwell equations also have to be split up into the anti-symmetric corresponding parts, with the restriction that the superposition of both spinors and corresponding equations equals the Maxwell equations (72). The Maxwell equations (72) are split up in the following way. The Maxwell equations (72-1) and (72-2) are split up in the Dirac equation with positive time derivatives.

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} - i \frac{\partial (\bar{\alpha}_i)}{\partial y} + \frac{\partial (\bar{\alpha}_i)}{\partial z} = \frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{1-A}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} - i \frac{\partial (\bar{\alpha}_i)}{\partial y} + \frac{\partial (\bar{\alpha}_i)}{\partial z} = \frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{1-B}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} + i \frac{\partial (\bar{\alpha}_i)}{\partial y} - \frac{\partial (\bar{\alpha}_i)}{\partial z} = \frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{2-A}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} + i \frac{\partial (\bar{\alpha}_i)}{\partial y} - \frac{\partial (\bar{\alpha}_i)}{\partial z} = \frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{2-B}
\]

The Maxwell equations (72-3) and (72-4) are split up into the Dirac equation with negative time derivatives:

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} - i \frac{\partial (\bar{\alpha}_i)}{\partial y} + \frac{\partial (\bar{\alpha}_i)}{\partial z} = -\frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{3-A}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} - i \frac{\partial (\bar{\alpha}_i)}{\partial y} + \frac{\partial (\bar{\alpha}_i)}{\partial z} = -\frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{3-B}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} + i \frac{\partial (\bar{\alpha}_i)}{\partial y} - \frac{\partial (\bar{\alpha}_i)}{\partial z} = -\frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{4-A}
\]

\[
\frac{\partial (\bar{\alpha}_i)}{\partial x} + i \frac{\partial (\bar{\alpha}_i)}{\partial y} - \frac{\partial (\bar{\alpha}_i)}{\partial z} = -\frac{1}{c} \frac{\partial (\bar{\alpha}_i)}{\partial t} \tag{4-B}
\]

Restricted to (confined) electromagnetic waves propagating along the z-axis, it follows from (21), (28) and (29) that the relations for the time- and spatial derivatives of the spinor components $e^\delta$ and $e^\gamma$ in (91) are:

\[
\begin{align*}
-\ih \frac{\partial e^{i\delta}}{\partial t} &= \gamma \Omega \mathcal{B} e^{i\delta} = W e^{i\delta} \\
-\ih \frac{\partial e^{i\delta}}{\partial \bar{x}} &= \gamma \Omega \mathcal{B} v_\perp e^{i\delta} = W v_\perp e^{i\delta} \\
-\ih \frac{\partial e^{i\gamma}}{\partial t} &= \gamma \Omega \mathcal{B} \frac{v_\perp e^{i\gamma}}{c^2} = W \frac{v_\perp}{c} e^{i\gamma} \\
-\ih \frac{\partial e^{i\gamma}}{\partial \bar{z}} &= \gamma \Omega \mathcal{B} \frac{e^{i\gamma}}{c} = W e^{i\gamma} \\
\frac{\partial e^{i\delta}}{\partial \bar{x}} &= \frac{\partial e^{i\delta}}{\partial \bar{x}} = \frac{\partial e^{i\gamma}}{\partial \bar{x}} = \frac{\partial e^{i\gamma}}{\partial \bar{y}} = 0
\end{align*}
\]  

Restricted to the conditions of propagation of the (confined) waves in the z-direction, it follows from (94):

\[
\begin{align*}
- \ih \frac{\partial e^{i\delta}}{\partial t} &= W \left[ 1 + \frac{v_\perp}{c} \right] e^{i\delta} \\
- \ih \frac{\partial e^{i\gamma}}{\partial t} &= W \left[ 1 - \frac{v_\perp}{c} \right] e^{i\gamma} \\
- \ih \frac{\partial e^{-i\delta}}{\partial t} &= -W \left[ 1 + \frac{v_\perp}{c} \right] e^{-i\delta} \\
- \ih \frac{\partial e^{-i\gamma}}{\partial t} &= -W \left[ 1 - \frac{v_\perp}{c} \right] e^{-i\gamma}
\end{align*}
\]

When the observer is at rest relative to the electromagnetic confinement, the time derivative of the spinor $\gamma^\pm$ is considered:

\[
\frac{4}{c} \frac{\partial}{\partial t} \gamma^\pm = \left( \begin{array}{c} i \frac{\partial (\Phi_k e^{i\delta})}{c \frac{\partial t}{} + \frac{1}{c} \frac{\partial (\Phi_k)}{\partial t} \gamma^\pm} \\
- i \frac{\partial (\Phi_k e^{-i\delta})}{c \frac{\partial t}{} + \frac{1}{c} \frac{\partial (\Phi_k)}{\partial t} \gamma^\pm} \\
- i \frac{\partial (\Phi_k e^{i\gamma})}{c \frac{\partial t}{} + \frac{1}{c} \frac{\partial (\Phi_k)}{\partial t} \gamma^\pm} \\
- i \frac{\partial (\Phi_k e^{-i\gamma})}{c \frac{\partial t}{} + \frac{1}{c} \frac{\partial (\Phi_k)}{\partial t} \gamma^\pm} \end{array} \right)
\]

in which the notation $m_e$ denotes an electromagnetic mass. In stationary conditions of the confinement yields $\partial_0 \Phi_k = 0$, on which condition substitution of (96) in (93) results in the stationary Maxwell equation for confined monochromatic radiation with rest frequency $\omega_0 = m_e c^2 / h_k$:

\[
\begin{align*}
\frac{\partial \tilde{u}_3}{\partial t} - i \frac{\partial \tilde{u}_3}{\partial \bar{y}} + \frac{\partial \tilde{u}_3}{\partial \bar{z}} + \frac{\im c}{h} \tilde{u}_1 &= 0 \tag{3-A} \\
\frac{\partial \tilde{u}_4}{\partial t} + i \frac{\partial \tilde{u}_4}{\partial \bar{y}} = - \frac{\im c}{h} \tilde{u}_1 &= 0 \tag{4-A} \\
\frac{\partial \tilde{u}_2}{\partial t} - i \frac{\partial \tilde{u}_2}{\partial \bar{y}} = - \frac{\im c}{h} \tilde{u}_1 &= 0 \tag{3-B} \\
\frac{\partial \tilde{u}_4}{\partial t} + i \frac{\partial \tilde{u}_4}{\partial \bar{y}} = - \frac{\im c}{h} \tilde{u}_1 &= 0 \tag{4-B}
\end{align*}
\]  

The non-stationary Maxwell equations for confined monochromatic radiation follows from (96), in which the time derivative is related to the mode fluctuation of the (confined) electromagnetic wave and is expressed by $\partial_0 \Phi_k$, which leads to the restriction that the time derivatives in (98) are not operating on the rest frequency $\gamma_0$ but only on the relative slow fluctuations expressed by $\partial_0 \Phi_k$. 

\[
\begin{align*}
- \ih \frac{\partial e^{i\delta}}{\partial \bar{t}} &= W \left[ 1 + \frac{v_\perp}{c} \right] e^{i\delta} \\
- \ih \frac{\partial e^{i\gamma}}{\partial \bar{t}} &= W \left[ 1 - \frac{v_\perp}{c} \right] e^{i\gamma} \\
- \ih \frac{\partial e^{-i\delta}}{\partial \bar{t}} &= -W \left[ 1 + \frac{v_\perp}{c} \right] e^{-i\delta} \\
- \ih \frac{\partial e^{-i\gamma}}{\partial \bar{t}} &= -W \left[ 1 - \frac{v_\perp}{c} \right] e^{-i\gamma} \\
\end{align*}
\]
A continuous model of matter based on AEONS

Within the scope of an electromagnetic model of matter, a particle/anti-particle combination is described by the superposition of both Maxwell equations (92) and (93), operating on the superposition of the spinors $\Psi^+$ and $\Psi^-$, which equals the Maxwell equation (72). The following matrices are introduced:

$$\begin{pmatrix}
\alpha_x \\
\alpha_y \\
\alpha_z
\end{pmatrix} = \begin{pmatrix}
0 & 0 & -ic \\
0 & 0 & -ic \\
-mc/b_E & mc/b_E & 0
\end{pmatrix}
(99)$$

Using (99) and (89): $\Psi^* + \Psi^+ = \overline{U} \Psi$, the Maxwell equations (72) are split up in the equations (92), which is presented as:

$$\begin{equation}
\frac{\partial}{\partial x} \Psi^+ + \frac{\partial}{\partial t} \Psi^+ = \overline{\alpha} \cdot \Psi^+ + \frac{imc}{b_E} \overline{\beta} \Psi^+ = 0
\end{equation}
(100)$$

and (93), which equals:

$$\begin{equation}
\frac{1}{c} \frac{\partial}{\partial t} \Psi^+ + \overline{\alpha} \cdot \Psi^+ + \frac{imc}{b_E} \overline{\beta} \Psi^+ = 0
\end{equation}
(101)$$

in which "$m_0$" is the total electromagnetic mass of a particle/anti-particle combination, originating from an electromagnetic confinement. The quantum mechanical (relativistic) Dirac equation is\(^{22}\) presented by:

$$\begin{equation}
\frac{1}{c} \frac{\partial}{\partial t} \Psi + \overline{\alpha} \cdot \Psi + \frac{imc}{b_E} \overline{\beta} \Psi = 0
\end{equation}
(102)$$

The summation of (100) and (101) operating on the spinor $\Psi^+ + \Psi^- + \Psi^*$ equals the Maxwell equation (72) operating on an electromagnetic (monochromatic) confinement with rest frequency $\omega_0 = mc^2 / b_E$.

**4. AUTO CONFINED ELECTROMAGNETIC ENTITIES (AEONS)**

The description of electro-magnetism employed in this section refers to an earlier idea of Lorentz. Namely the basic idea that the observed relativistic effects of space and time transformations are essentially based on electromagnetic transformations which are in this theory considered as the basic fundamentals of space and time. This implies that the idea of a fundamental aether in this section is not principally excluded. The theory however requires that the rest mass of the hypothetical aether is zero, and that the observed energy has to be described in terms of an aether tension due to an electromagnetic effect, while this tension is represented by a specific local mass density due to an electromagnetic energy density. This implies that in absolute empty space (without the presence of any energy) the aether does not physically exist, but is created by the presence of electromagnetic energy.

The theory requires that the observed aether phenomena do not contradict special or general relativity. This requirement can only be fulfilled by the assumption that observers are essentially made of Aeons combinations, with the observer's own system variables $G$ in which the time is determined by the rest frequency $T_0$ of the concerned Aeons and space is prescribed by the corresponding rest wavelengths, indicated by $k_0$ which transform according to (25).

Only in that special circumstance, space and time, as discerned by the observer, are fundamentally supported by electromagnetic effects and the speed of light, described by an electromagnetic effect, will be observed as being independent of the velocity relative to the observer.

The model of an aether which carries the electromagnetic energy transport implies a wave equation which is comparable to an acoustic wave equation in a gas. The relativistic specific local mass of the aether is indicated by $\rho_{EM}(x,t)$ and the relativistic local elasticity of the aether is indicated as $\mathcal{E}_{EM}(x,t)$ due to the gradient of the radiation pressure, caused by the local energy density "$\omega$", a volume element "dV" of electromagnetic energy is accelerated in the direction of the gradient of the radiation pressure. This effect is described by the relativistic acoustic aether wave equation which is rather similar to the acoustic wave equation for sound waves in gases, in which the acoustic phenomena are described by the dynamic sound pressure $\rho_s$, which is related to the local dynamic potential energy density of the gas. The acoustic wave equation for sound waves in gases is:

$$\frac{1}{c} \nabla^2 \rho_s(x,t) = \rho_c \frac{\partial^2 \rho_s(x,t)}{\partial t^2}$$
(103)

in which $\rho_c(x,t)$ is the local specific mass of the gas and $\mathcal{E}(x,t)$ is the local elasticity of the gas. By multiplying both sides of equation (103) with $-1/\omega_0$ in which $\omega_0$ is the unit of electric charge density, an electromagnetic equivalent for the local dynamic potential energy density of the gas is obtained by the electric potential $V(x,t)$, which transforms due to relativistic effects into $V(x,t) = [\gamma(\mathcal{E}(x,t)] + [\gamma C(x,t)] = \gamma_x$ and a Lorentz transformed potential 4-vector is observed which equals $[\gamma(\mathcal{E}(x,t)] + [\gamma C(x,t)] = \gamma_x$, $\mathcal{E}$ and $\mathcal{C}$. Using this substitution, equation (103) transforms into the relativistic acoustic aether wave equation, in which the term acoustic indicates that energy density fluctuations propagate due to an elastic effect:
The elasticity of electromagnetic radiation is determined by the compression of confined radiation over a small distance and measuring the radiation pressure which has to be counterbalanced during the compression. The quotient of the relative deformation and the applied mechanical pressure is indicated as the elasticity of confined radiation and equals the reciprocal of the energy density \( w \). The relativistic specific mass of the aether equals \( w/ c^2 \). Substituting these values in (104) results in:

\[
\frac{1}{2} \nabla^2 \varphi_{EM}(\vec{x}, t) = \rho_{EM} \frac{\partial^2 \varphi_{EM}(\vec{x}, t)}{\partial t^2} \quad (104)
\]

The material-like treatment of light is in correspondence with Maxwell's theory because (105) is identical to the electromagnetic source equation in vacuum

\[
\Box \varphi_{EM}(\vec{x}, t) = \mu \frac{\partial^2 \varphi_{EM}(\vec{x}, t)}{\partial t^2} \quad (105)
\]

in which \( \Box = \nabla^2 \) is the d'Alembertian operator and equals:

\[
\Box = -\nabla^2 = \frac{1}{c^2} \frac{\partial^2}{\partial t^2} - \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right) \quad (107)
\]

The aether model with the restriction that the rest mass of the aether is zero in the absence of energy does not violate relativity. When an observer moves relative to an electromagnetic wave, a Lorentz transformed specific mass and a Lorentz transformed elasticity of the aether are observed, which implies that independent of the velocity of the observer still the relative velocity \( v/c \) of the electromagnetic phenomena is measured. This accords with relativity. This model suggests that in the absence of any energy also the aether disappears which is in correspondence with Mach's principle that "If there is no matter then there is no geometry". The idea of an electromagnetic aether is also used in the description of the effect that the velocity of electromagnetic waves is lowered in matter. General relativity cannot explain this effect because the concerned mass is much too small to cause measurable space-time curvature. The only possible explanation is to couple the electromagnetic field mass of electrons to the electromagnetic aether mass in (104) while the aether elasticity changes a little due to the electromagnetic coupling of the electron to the atom. This lowers the speed of light in materials effectively. Formula (105) is derived rather to demonstrate that an aether theory does not inevitably contradict Maxwell or relativity than it is a necessary equation to demonstrate the possibility of Aemons.

An important aspect of Aemons is inertia, or passive gravitational mass(36,37). To explain inertia a simplified model is used in which radiation is confined e.g. between perfect reflecting mirrors. The radiation pressure on the confining system equals \( w/4 \), in which \( w \) represents the sum of the electromagnetic wave energy density and the confining energy density, and in an inertial system the internal forces counterbalance. During an acceleration \( \ddot{a} \) of the system the radiation pressure is transformed. The Poynting 4-vector, describing the confined radiation, is transformed by:

\[
\dot{S}_\mu' = \dot{S}_\mu - \dot{\gamma}_\mu^\alpha \dot{S}_\alpha \quad (108)
\]

in which follows from (10-A) up to and including (15-A) and (51-A) in the appendix. During the acceleration the radiation pressure \( \dot{S}_\mu \) on the confining system towards the acceleration is increased and the radiation pressure \( \dot{P} \) on the opposite part is decreased. In a 1-dimensional reduction (108) can be written as:

\[
\dot{S}_1' = \left( \frac{1 + v/c}{1 - v/c} \right) \dot{S}_1 + \left( \frac{1 - v/c}{1 + v/c} \right) \dot{S}_1 \quad (109)
\]

This results in a difference of the radiation pressure(28,29) \( \dot{S} \) and \( \dot{P} \) during the acceleration. The resulting force \( F_R \) on the system during the acceleration equals:

\[
F_R = \dot{F} + \dot{F}_R = \left( \frac{1 + v/c}{1 - v/c} - \frac{1 - v/c}{1 + v/c} \right) \frac{w}{c} \quad (110)
\]

in which \( 7 \) is the surface of the confining system. During the acceleration in a time interval \( \Delta t \) the waves travel from one mirror to the opposite one which is at a distance \( l \) away from the other. For that reason the travelling time \( \Delta t \) equals \( l/c \). At uniform acceleration \( a \) the velocity \( v \) is increased with \( a \Delta t \) during the interval \( \Delta t \). Substituting in (77) results in:

\[
F_R = \left( \frac{1 + a l/c^2}{1 - a l/c^2} - \frac{1 - a l/c^2}{1 + a l/c^2} \right) \frac{w A}{4} \quad (111)
\]

At accelerations \( a < c^2/l \) equation (111) is approximately equal to Newton's law \( F_R = Wa/c^2 \) in which the passive gravitational mass equals \( W/ c^2 \). This implies that the model of confined radiation obeys elementary physical laws and gives a reasonable explanation for elementary material aspects of AEONS.

An important aspect of general relativity, the elementary coupling between passive gravitational mass, presented in (111), and active gravitational mass which is the origin of a gravitational field, is the basic of the description of GEONS(24) (Gravitational Electromagnetic Entities). Equation (111) shows that a gradient in the energy density, opposite to the acceleration, causes passive gravitational mass. Subsequently confined electromagnetic radiation, situated in a gravitational field, will present a gradient of the energy density due to this gravitation, which results in a force opposite to the direction of the gravitational field.

This idea is worked out in a description of a static electromagnetic aether self-confinement in which electromagnetic waves propagate comparable to a cloud of gas in which acoustic waves propagate, described by (105) and (103) respectively, in which the term acoustic concerns the propagation of energy density fluctuations due to an elastic effect.
Equations (104) and (105) describe electromagnetism as an acoustic 4-vector oriented phenomenon in a medium with a mass density proportional to the energy density of the confined phenomenon and consequently a rest mass equal to zero, this in contradiction to equation (103) which describes an acoustic scalar phenomenon in a medium with finite rest mass mainly independent of the energy density of the confined acoustic wave in e.g. a gas cloud. The relativistic effects of the electromagnetic waves propagating in the Geons are in this model observed as probability waves and described by (56) and (102).

Because gravitational forces will not exclusively lead to Geons, gravity is in this short illustration treated by a Poisson equation instead of the more valid Einstein Maxwell equations. The description of the electromagnetic aether self-confinement concerns a static phenomenon due to an extremely strong energy density, which is responsible for the confinement. The treated equations are comparable to the equations concerning static gas clouds in free space and will not describe the confining wave equation itself, but only the stability condition for electromagnetic self-confinement.

A simplified approach to the gravitational field generated by an arbitrary mass distribution has been adopted for gravitational self-confinement. To determine the gravitational field a Poisson equation has been formulated for the gravitational potential 
\[ V_g(x) = \frac{M}{4\pi \rho_g(x)} \]
caused by a mass density distribution \( \rho_g(x) \):

\[ \nabla^2 V_g(x) = -4\pi G \rho_g(x) \quad (112) \]

where "G" is the gravitational constant in (11). If the mass distribution relates to a point mass "M", we have \( \rho_g(x) = M G(x) \). The solution for the gravitational potential is then: \( V_g(r) = -GM/r \) in which "r" is the distance related to the point mass M. If the electromagnetic mass density, defined in (47) and (49), is substituted in (112) this can then be written as:

\[ \nabla^2 V_g(x) = -\frac{1}{2} \kappa c^2 \Psi_R^2 \quad (113) \]

in which \( \kappa \) is coupling constant in (11) and expresses the coupling of an electromagnetic energy density to a gravitational field. The solution of (113) is given by:

\[ V_g(x) = G \int_{vol} \frac{\Psi_R^2(y)}{|x-y|} dV \quad (114) \]

The model assumes an equilibrium between the repulsive forces, caused by the gradient of the radiation pressure and the attractive forces generated by the mass of the confined electromagnetic radiation. The occurrence of the repulsive forces in the confined electromagnetic radiation can be explained as follows. In a thought experiment the assumption is made of a double-sided perfectly reflecting mirror of thickness \( x \). A plane electromagnetic wave with energy density "w+" w moves the left side of the mirror and radiation energy with an energy density "w" moves the right side. If the surface area of the mirror is "A" the resulting force on the mirror is directed to the right and is equal to A) w. If the system is situated in a gravitational field with gravitational potential \( V_g \), a layer thickness of electromagnetic radiation with thickness "x" and a surface area "A" experiences an attractive force equal to \( (wA) x/c^2(\nabla V_g/ M) \), which concept is in basic correspondence with (48-A). In the thought experiment, the mirror is now replaced by electromagnetic radiation with energy density "w". In equilibrium, the rightwards-directed forces, as the result of a gradient in the electromagnetic energy density, will be compensated by the leftwards-directed forces because of a gradient in the gravitational potential. In equilibrium we have the equation:

\[ \nabla^2 \Psi_R = \frac{\nabla \Psi_R \cdot \nabla \Psi_R}{\Psi_R^2} - \frac{\kappa \Psi_R^2}{4} \Psi_R \quad (116) \]

Relation (116) expresses a condition which must be satisfied by a self-confined electromagnetic wave in radial direction under the influence of a self-generated gravitational field. A particular solution which satisfies (116) is:

\[ \Psi_R = \frac{2}{\sqrt{\kappa}} \frac{1}{r} = 1.5 \times 10^{33} \frac{1}{r} \quad (117) \]

Equation (117) shows the energy density required for gravitational self-confinement. This energy density should be in the order of \( 10^{33} [J/m^3] \) at the surface of an electromagnetic self-confinement with, for example, the dimensions of a proton. In view of the small mass of elementary particles, the electromagnetic self-confinement should take place in a very thin energy shell on the surface of the confinement. Because of the local extremely high electromagnetic radiation pressure of \( 10^{33} [N/m^2] \) a gravitational electromagnetic self-confinement will behave like an extremely hard, non-deformable elementary particle that can only be split in collision experiments.

It follows from equation (117) and (3-A) that for a gravitational self confinement in a spherical shell (azimuthal quantum number \( \ell = 0 \)) at a radius of \( 1.6 \times 10^{33} [m] \) the required averaged field intensity \( \bar{E} = 13.5 \times 10^{44} [V/m] \) which equals in electro-static units \( \bar{E} = 4.5 \times 10^{10} [esu/cm] \) (Table 1). Gravitational self confinements have already been described by Wheeler (24-25) who introduced the GEONS (Gravitational Electromagnetic Entities) which describe gravitational confined radiation in toroidal confinements. The table below presents the values calculated by Wheeler, by solving the Einstein - Maxwell equations for the toroidal gravitational self confinements. The presented values in table 1 for the averaged electric field intensity are only comparable with the results from equation (117) for low azimuthal quantum number \( \ell = 0 \).
Geons at smaller dimensions are quantum objects and need a different mathematical approach. In the demonstrated simplified example in (116), gravity is only used to confine electromagnetic radiation in a way as gas clouds are confined by their own gravitational field. The mass however of an elementary particle is too small for confining gravitationally electromagnetic radiation in a reasonable way. An alternative way of confinement like "electro-magneto-static" confinement is required.

In an identical way as GEONS are described by the gravitational equilibrium equation (115) or its equivalence (116), EEONS (Electro-Magneto-Static Confined Electromagnetic Entities) are described by the electro-magneto-static equilibrium equation (120). The electro-magneto-static balance equation follows from the energy-momentum tensor (8), which can be written as:

\[
T^{ab} = \frac{1}{2} \left( \epsilon E_a E_b + \frac{1}{\mu} B_a B_b - \delta_{ab} \rho \right)
\]  

in which \(\rho\) is the energy density. From (45-A) and (47-A) in the appendix it follows that the electro-magneto-static balance equation equals:

\[
f^a = \partial_b T^{ab} = 0
\]

which can be written as:

\[
\epsilon_\circ \left[ \vec{E}, \vec{E} \right] \ast \left[ \vec{E}, \vec{E} \right] = \frac{1}{\mu} \left[ \vec{B}, \vec{B} \right] \ast \left[ \vec{B}, \vec{B} \right]
\]

As an example a 3-dimensional confinement is chosen in which the vector wave function \(\Phi(r, \theta, \phi, t)\) in (13) or (3-A) is presented in spherical coordinates and equals:

\[
\Phi(r, \theta, \phi, t) = \begin{pmatrix}
\Phi_r \\
\Phi_\theta \\
\Phi_\phi
\end{pmatrix} = \sqrt{\frac{\epsilon}{2}} \begin{pmatrix}
\frac{1}{R(r)} Y_{m}(\theta, \phi) \\
0 \\
R(r) Y_{m}(\theta, \phi)
\end{pmatrix}
\]  

in which \(R(r) Y_{m}(\theta, \phi, t)\) is a real function. It follows from (135) that in this type of confinement the electric field intensity is oriented along the radial coordinate. The component of \(\Phi(r, \theta, \phi, t)\) along the azimuthal direction equals zero. The magnetic field intensity is oriented along the \(\theta\)-direction. The frequency of the confinement is determined by the demand of continuity of the electric and magnetic field intensities so that \(n = 8\) equals the circumference of the confinement.

In analogy with the gravitational confinement of electromagnetic radiation, described earlier by Wheeler(24), an electro-magneto-static confinement of light requires an equilibrium between the radial outwardly pointing radiation pressure and the radial inwardly pointing electro-magneto-static forces. The radial outwardly pointing radiation pressure equals:

\[
- \nabla \rho = - \epsilon R(r) Y_{m}^{2}(\theta, \phi) \partial R(r) \partial r
\]

Because in this type of confinement the magnetic field intensity is oriented perpendicular to the radial direction, only the electric field intensity is supplying the radial inwardly pointing forces to counterbalance the radial radiation pressure. It follows from equation because every confined wave has to be considered as the superposition of waves propagating away from the observer and waves in opposite direction. For that reason (8A) is written as:

\[
\vec{E}(x, \omega) = \frac{E_0}{2} \left[ \cos(\omega t - kx) + \cos(\omega t + kx) \right]
\]  

The Lorentz transformation depends on the relative velocity. For waves propagating towards the observer (the velocity of the observer relative to the confining system is \(+\nu\)) an increased frequency \(\omega'\) is measured while waves moving in opposite direction are observed with a decreased frequency \(\omega'\). The shifted frequency \(\omega'\) of the waves moving towards the observer is described by the zero component of the wave 4-vector (24), which transforms as follows:

\[
\gamma \omega' = \gamma k' = \frac{\gamma L_0}{c} k^a = \frac{\gamma \omega}{c} \left( 1 + \frac{\nu}{c} \right)
\]

in which \(\gamma L_0\) is given in (58A). In a comparable way the x-component "k" of the wave 4-vector \(k^i\) transforms as follows:

\[
\gamma k' = \gamma k' = \frac{\gamma L_0}{c} k^b = \frac{\gamma \omega}{c} \left( 1 - \frac{\nu}{c} \right)
\]

for the waves moving toward the observer, and as follows

\[
\gamma k' = \gamma k' = \frac{\gamma L_0}{c} k^b = \frac{\gamma \omega}{c} \left( 1 - \frac{\nu}{c} \right)
\]

for the waves moving in the same direction as the observer. The coordinate \(x\), which is the 1-component of the Minkowski 4-vector \(x^a\) will transform thus:
A continuous model of matter based on AEONS

\[ x' = L_a \cdot x^a = \gamma (x - vt) \] (128A)

(The coordinate system G is connected to the moving observer and the system G is connected to the confining system) The coordinateict, which is the 0-component of the 4-vector \( x^a \) will transform thus:

\[ ixt' = L_0 \cdot x^a = i\gamma \left( t - \frac{vx}{c^2} \right) \] (129A)

The first part of (9A) presents the waves travelling in the positive \( x \)-direction and are moving in the same direction as the observer. They will be observed with a lowered frequency. The second term in (9A) presents the waves travelling towards the observer and are measured with an increased frequency. The observer perceives the transformed wave:

\[ \vec{E}(\vec{x}, t') = \gamma E_0 \left[ \cos(\omega t' - kx') - \cos(\omega t' + kx') \right] \] (130A)

Substituting (10A) up to and including (13A) in (16A) results in:

\[ \vec{E}(\vec{x}, t') = \frac{\gamma E_0}{2} \left[ \cos(\gamma \omega t' - \gamma kx') - \gamma k(1 - \frac{\gamma}{c}x') \right] \] (131A)

Subsequently (17A) is written in a way comparable with (8A). Using the simple goniometric equation:

\[ \cos(p) - \cos(q) = 2 \sin\left( \frac{p + q}{2} \right) \sin\left( \frac{q - p}{2} \right) \] (132A)

(17A) can be written as:

\[ \vec{E}(\vec{x}, t') = \gamma E_0 \left[ \sin(\gamma \omega t') + \frac{\gamma kx'}{c} \right] \sin(\gamma kx') + \frac{\gamma \omega x'}{c} \] (133A)

Introducing the phases \( \theta \) and \( \phi \), (19A) is presented by:

\[ \vec{E}(\vec{x}, t') = \gamma E_0 \sin(\beta) \sin(\alpha) \] (134A)

Equation (20A) is comparable with the first part of (27) (in the article), while \( \theta \) and \( \phi \) are presented in a comparable way in (28) and (29) for a 1-dimensional wave. The second part of (27) follows from the complete Lorentz transformation for electromagnetic fields which implies that a part (proportional to \( v/c \)) of an electric field is transformed into a magnetic field and a part of a magnetic field (proportional to \( v/c \)) is transformed into an electric field due to the transformation of the 4-potential.

The wave in (19A) is propagating with an apparent phase velocity \( v_p \) related to the phase \( \phi \), indicated as \( v_p \) [149],

\[ v_p = \frac{x'}{t'} = -\frac{\gamma \omega}{\gamma k v/c} \] (135A)

Using the basic relation \( k = T/c \), (21A) changes into:

\[ v_p = -\frac{c^2}{\nu} \] (136A)

In the original article the relative velocity between the observer and the confining system is indicated as the group velocity \( v_G \) and (22A) is comparable with (30). The \( -\) sign indicates that the observed wave propagates with an apparent phase velocity, inversely proportional to the momentum of the confined wave, towards the observer. From the phase \( \phi \) in (19A) it follows that the observed wavelength \( \lambda' \) equals:

\[ \lambda' = \frac{\lambda}{\gamma} \]

that quantum-mechanical probability is possibly originated in the relativistic effects of AEONS and that electromagnetic self-confinement is a physical possibility without contradicting Maxwell or Relativity. The fact that the Maxwell Equations (100) and (101) demonstrate a remarkable correspondence with the Dirac equation (102) indicates an electromagnetic origin of matter.

APPENDIX: CLASSICAL ELECTROMAGNETISM RELATED TO RELATIVITY AND QUANTUM MECHANICS

This appendix presents a brief view of classical electromagnetism in relation to special relativity and quantum mechanics. A well known equation in quantum mechanics is the law of conservation of probability, presented as:

\[ \frac{\partial}{\partial t} Q + \nabla \cdot Q = 0 \] (1A)

in which \( Q \) is the probability density and equals \( Q^* \) and \( \sum \) is the probability density flux. The continuity equation for electromagnetic radiation, given in equation (42) in the article and in (63A) in the appendix, is presented as a basic equivalent for the law of conservation for probability in which the electromagnetic energy density \( \epsilon \) is an equivalent for the probability density and the Poynting vector \( \overrightarrow{S} \) describing the energy density flux of electromagnetic radiation, turns out to be the equivalent for the probability density flux, presented by \( \sum \).

\[ \frac{\partial}{\partial t} \epsilon + \nabla \cdot \overrightarrow{S} = 0 \] (2A)

By introducing the equivalence of both equations, the law of conservation of probability transforms into the law of conservation of energy. The continuity equation (42) (in the article) is relativistically transformed into (56), which equation has a clear correspondence with the Schrödinger equation for probability waves. The relation between probability and electromagnetic energy density is created by the introduction of the electromagnetic vector wave functions \( \overrightarrow{E}(\vec{x}, \vec{t}) \) and \( \overrightarrow{B}(\vec{x}, \vec{t}) \) in (13). It is important to notice that both vector wave functions are complex and have no physical meaning. They are in no way related to a real electric or magnetic field and physically both hypothetical vector wave functions do not
exist. Substitution of (1) and (2) in (13), in the absence of a gravitational field, results in:

$$\tilde{\phi}(x,t) = \sqrt{\frac{1}{\mu}} \left( B + i E \right)$$  \hspace{1cm} (3A)$$

The scalar product of the vector wave functions $\tilde{\phi}(x,t)$ and $\tilde{\phi}^*(x,t)$ times the square of the velocity of light is a real physical quantity and equals the electromagnetic energy density "w":

$$w(x,t) = c^2 \tilde{\phi}(x,t) \cdot \tilde{\phi}^*(x,t) = \frac{1}{2} \left( B^2 \mu + c^2 E^2 \right)$$  \hspace{1cm} (4A)$$

This equation is related to the definition of the quantum mechanical probability density $w_p$ for which quantity prevails:

The equations (4A) and (5A) demonstrate an initial correspondence between quantum mechanical probability waves and electromagnetic waves. The electromagnetic energy density flux is presented by the Poynting vector $\vec{S}$ and equals:

Substituting (4A) into (2A) results in an equation for the hypothetical non-existing vector waves functions $\tilde{\phi}(x,t)$ and $\tilde{\phi}^*(x,t)$, which describes a physical real process of the conservation of electromagnetic energy.

$$\frac{\partial}{\partial t} \left( \tilde{\phi} \cdot \tilde{\phi}^* \right) + i \epsilon \nabla \cdot \left( \tilde{\phi}^* \times \tilde{\phi} \right) = 0$$  \hspace{1cm} (7A)$$

In section (2) the Schrödinger wave function is relativistically derived from equation (7A) in a comparable way as in section (3) the relativistic Dirac equation is derived from the same equation (7A). This demonstrates a further correspondence between the hypothetical electromagnetic complex wave functions $\tilde{\phi}(x,t)$ and $\tilde{\phi}^*(x,t)$ and the quantum mechanical complex probability wave functions $\Psi(x,t)$ and $\Psi^*(x,t)$, while both equations (1A) and (2A) describe real physical processes.

To clarify the relativistic derivation of the Schrödinger wave equation from the continuity equation (2A), a brief introduction is given in special relativity which describes the transformations of space, time and electromagnetism in any inertial system. Because a uniform velocity relative to an object in a coordinate system $G$ can be described as a one dimensional movement by a rotation of the coordinate system, an explanation is given for a one dimensional Lorentz transformation along the $1$-axis which is indicated in the following as $x$-axis.

A monochromatic electromagnetic wave with frequency $\nu$ and amplitude $E_0$ is considered, confined in an arbitrary system. The considered one dimension (indicated as the $x$-axis) is parallel to the observer's direction of movement. In this description of 1-dimension a confined electromagnetic wave can be described as:

$$\vec{E}(x,t) = \vec{E}_0 \sin(\omega t + \sin(kx))$$  \hspace{1cm} (9A)$$

In which "k" equals $2\pi \frac{\lambda}{c}$ in which $\lambda$ is the wavelength of the confined monochromatic wave. When an observer is moving relative to the confined wave (along the $x$-axis), a transformed frequency, wavelength, $x$-coordinate and $t$-coordinate are observed. It is impossible to transform equation (1) by a Lorentz transformation, because every confined wave has to be considered as the superposition of waves propagating away from the observer and waves in opposite direction. For that reason (8A) is written as:

$$\tilde{E}(x,t) = \frac{\tilde{E}_0}{2} \left[ \cos(\omega t - kx) - \cos(\omega t + kx) \right]$$  \hspace{1cm} (9A)$$

The Lorentz transformation depends on the relative velocity. For waves propagating towards the observer (the velocity of the observer relative to the confining system is $v^+$) an increased frequency $\nu'$ is measured while waves moving in opposite direction are observed with a decreased frequency $\nu$. The shifted frequency of the waves moving towards the observer is described by the zero component of the wave 4-vector (24), which transforms as follows:

$$\nu' = \nu^0 = \frac{\nu^0}{\gamma^2} \left( 1 + \frac{v}{c} \right)$$  \hspace{1cm} (10A)$$

in which $\gamma$ is the Lorentz transformation tensor, presented in (57A). The frequency of the waves moving away from the observer is observed as $\nu'$ and equal to:

$$\nu' = \frac{\nu^0}{\gamma^2} \left( 1 - \frac{v}{c} \right)$$  \hspace{1cm} (11A)$$

in which $\gamma$ is given in (58A). In a comparable way the $x$-component "k" of the wave 4-vector $k^x$ transforms as follows:

$$k^x' = \frac{k^x}{\gamma} = \frac{\nu^0}{c} \frac{k^x}{\gamma^2} \left( 1 + \frac{v}{c} \right)$$  \hspace{1cm} (12A)$$

for the waves moving toward the observer, and as follows

$$k^x' = \frac{k^x}{\gamma} = \frac{\nu^0}{c} \frac{k^x}{\gamma^2} \left( 1 - \frac{v}{c} \right)$$  \hspace{1cm} (13A)$$

for the waves moving in the same direction as the observer. The coordinate $x$, which is the 1-component of the Minkowski 4-vector $x^a$ will transform thus:

$$x^t = L^t_\nu x^\nu = \gamma (x - vt)$$  \hspace{1cm} (14A)$$

(The coordinate system $G$ is connected to the moving observer and the system $G'$ is connected to the confining system) The coordinate $ict$, which is the 0-component of the 4-vector $x^a$ will transform thus:

$$ict' = L^0_\nu x^\nu = i \gamma \left( t - \frac{vx}{c^2} \right)$$  \hspace{1cm} (15A)$$

The first part of (9A) presents the waves travelling in the positive $x$-direction and are moving in the same direction as the observer. They will be observed with a lowered frequency. The second term in (9A) presents the waves travelling towards the observer and are measured with an increased frequency. The observer perceives the transformed wave:
A continuous model of matter based on AEONS

\[ \bar{E}(x', t') = \frac{\gamma E_0}{2} \left[ \cos(\omega_0 t' - k x') \cos(\omega_1 t' + k_0 x') \right] \] (16A)

Substituting (10A) up to and including (13A) in (16A) results in:

\[ \bar{E}(x', t') = \frac{\gamma E_0}{2} \left[ \cos(\omega(1 - \frac{v}{c}) t' - \gamma k(1 + \frac{v}{c}) x') \right] \] (17A)

Subsequently, using \( \frac{\gamma E_0}{2} \) instead of \( \gamma E_0 \) written in a way comparable with (8A). Using the simple goniometric equation:

\[ \cos(p) - \cos(q) = 2 \sin \left( \frac{p + q}{2} \right) \sin \left( \frac{q - p}{2} \right) \] (18A)

(17A) can be written as:

\[ \bar{E}'(x', t') = \gamma E_0 \sin(\beta) \sin(\alpha) \] (19A)

Introducing the phases \( \beta \) and \( \alpha \), (19A) is presented by:

\[ \bar{E}'(x', t') = \gamma E_0 \sin(\beta) \sin(\alpha) \] (20A)

Equation (20A) is comparable with the first part of (27) (in the article), while \( \alpha \) and \( \beta \) are presented in a comparable way in (28) and (29) for a 1-dimensional wave. The second part of (27) follows from the complete Lorentz transformation for electromagnetic fields which implies that a part (proportional to \( v/c \)) of an electric field is transformed into a magnetic field and a part of a magnetic field (proportional to \( v/c \)) is transformed into an electric field due to the transformation of the 4-potential.

The wave in (19A) is propagating with an apparent phase velocity \( v_p \) related to the phase \( \beta \), indicated as \( v_p \):

\[ v_p = \frac{k'}{t'} = -\frac{\gamma \omega}{\gamma k v/c} \] (21A)

Using the basic relation \( k = T/c \), (21A) changes into:

\[ v_p = -\frac{c^2}{c} v \] (22A)

In the original article the relative velocity between the observer and the confining system is indicated as the group velocity \( v_g \) and (22A) is comparable with (30). The \( -\) sign indicates that the observed wave propagates with an apparent phase velocity, inversely proportional to the momentum of the confined wave, towards the observer. From the phase \( \beta \) in (19A) it follows that the observed wavelength \( \lambda \) equals:

\[ \lambda = \frac{2\pi}{k'} = \frac{2\pi c}{\gamma k v/c} = \frac{m c^2}{\gamma n \nu} = \frac{W_0}{\beta} \] (23A)

substituting (21) in (23A) results in:

\[ \lambda = \frac{h_p}{\beta} \] (24A)

Equation (24A) shows that the observed wavelength \( \lambda \) is inversely proportional to the momentum "\( p \)" of the confined electromagnetic radiation which is a characteristic phenomenon for probability waves. Substituting (14A) and (15A) into (19A) yields:

\[ \beta = \left( \frac{\gamma k x' + \gamma \omega t'}{c} \right) = \left[ \gamma^2 \omega (1 - \frac{v x}{c^2}) + \gamma^2 \omega (1 - \frac{v t}{c^2}) \right] = \omega t \] (25A)

This means that the phase \( \beta \) is Lorentz invariant. In a comparable way the phase \( \alpha \) equals:

\[ \alpha = \left( \frac{\gamma k x' - \gamma \omega t'}{c} \right) = \left[ \gamma^2 k (1 - \frac{v x}{c^2}) + \gamma^2 \omega (1 - \frac{v t}{c^2}) \right] = k \] (26A)

Equation (26A) proves that also the phase \( \alpha \) is Lorentz invariant, which is a necessary requirement for a Lorentz transformation.

To derive the Schrödinger equation (56) from (7A) relativistically, a Lorentz transformation is required of the Maxwell energy-momentum tensor (8). Substituting (1) and (2) into (4) (in the article), the Maxwell tensor is presented by:

\[ F_{ab} = \begin{vmatrix} 0 & -\frac{i}{c} E_x & -\frac{i}{c} E_y & -\frac{i}{c} E_z \\ \frac{i}{c} E_x & 0 & -B_y & B_z \\ \frac{i}{c} E_y & B_y & 0 & -B_z \\ \frac{i}{c} E_z & -B_y & B_z & 0 \end{vmatrix} \] (27A)

In non-relativistic units the inhomogeneous Maxwell equation (6) becomes:

\[ \frac{\partial}{\partial x} F_{ab} = -\mu_0 j_a \] (28A)

Substituting (5) in the covariant Maxwell equation (28A) and using (27A), this results in the inhomogeneous Maxwell equation for "a" varying from 1 and "b" varying from 0 up to and including 3:

\[ \nabla \times \vec{B} = \frac{1}{c^2} \frac{\partial \vec{E}}{\partial t} = \mu_0 \vec{j} \] (29A)

and for "a" = 0 and "b" varying from 1 up to and including 3 for the inhomogeneous Maxwell equation:

\[ \nabla \cdot \vec{E} = \frac{\rho}{\epsilon_0} \] (30A)

The homogeneous Maxwell equations are presented by (7). Using (27A) and for a = 1, c = 2 and b = 3, this results in:

\[ \nabla \cdot \vec{B} = 0 \] (31A)

and for the values a = 0 and b and c varying from 1 up to and including 3, (7) results in:

\[ \nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \] (32A)
In the absence of gravity the energy-momentum tensor (8) reduces for non-relativistic units to:

\[ T_{ab} = \frac{1}{\mu_0} \left( F_{ac} F_{cb} + \frac{1}{4} \delta_{ab} F_{cd} F^{cd} \right) \]  \hspace{1cm} (33A)

Substituting (27A) in (33A) results that \( T_{00} \) equals the electromagnetic energy density \( \omega \):

\[ T_{00} = \frac{1}{2} \left( \epsilon_0 E^2 + \frac{B^2}{\mu_0} \right) = \omega \]  \hspace{1cm} (34A)

and for the terms \( (T_{01}, T_{02}, T_{03}) \):

\[ \{ T_{01}, T_{02}, T_{03} \} = \frac{-i}{c} \left( \vec{S}_\alpha \right) \]  \hspace{1cm} (35A)

in which \( \vec{S} \) is the Poynting vector \( \vec{S} = \vec{E} \times \vec{B} / \mu_0 \). In the absence of external confining forces, the row \( ic T_{ab} \) (for \( a = 0 \)) in the tensor (33A), transforms like a \( (\text{pseudo-}) \) 4-vector and is introduced as the Poynting 4-vector in (36), which modulus is Lorentz invariant under inertial movements relative to the observer.

Substituting the Lorentz invariant quantities: the interval \( ds = \sqrt{-x^a x^a} \), the restmass \( m_0 \), the speed of light \( c \), the scalar product \( A x^a \), and the electric charge \( q \) in the action integral \( S \), results in:

\[ S = \int_{t_\text{1}}^{t_\text{2}} \left[ -m_0 c d s + q \left( \vec{A} \cdot d \vec{r} - q d t \right) \right] \]  \hspace{1cm} (36A)

Separating the time-interval \( d t \) in (36A) results in:

\[ S = \int_{t_\text{1}}^{t_\text{2}} \left[ -m_0 c \sqrt{1 - \frac{\vec{v}^2}{c^2}} + q \left( \vec{A} \cdot d \vec{v} - q d t \right) \right] d t = \int_{t_\text{1}}^{t_\text{2}} L d t \]  \hspace{1cm} (37A)

in which "L" is the Lagrangian. The action integral "S" is zero over a small time-interval \( t_\text{1} - t_\text{2} \) when "L" satisfies the Euler-Lagrange equation:

\[ \frac{d}{d t} \left( \frac{\partial L}{\partial \vec{v}} \right) - \frac{\partial L}{\partial \vec{v}} = 0 \]  \hspace{1cm} (38A)

Equation (38A) is split up into two parts:

\[ \frac{\partial L}{\partial \vec{v}} = \frac{m_0 \vec{v}}{\sqrt{1 - \frac{\vec{v}^2}{c^2}}} + q \vec{A} = \rho \vec{v} + q \vec{A} \]  \hspace{1cm} (39A)

and:

\[ \frac{\partial L}{\partial \vec{r}} = \vec{v} \cdot \vec{L} = q \left( \vec{v} \cdot \vec{A} \right) - \vec{v} \cdot \vec{q} \]  \hspace{1cm} (40A)

Substituting (39A) and (40A) into (38A) leads to the Lorentz invariant equation:

\[ \frac{d \vec{r}}{d t} = -\frac{q}{\mu_0} \frac{\partial \vec{A}}{\partial t} - q \vec{v} \vec{\nabla} \varphi + q \left( \vec{v} \times \vec{A} \right) \]  \hspace{1cm} (41A)

Substituting (1) and (2) in (41A) gives the Lorentz invariant equation for the mechanical force \( \vec{F} \) acting on a charged mass in an electromagnetic field:

\[ \vec{F} = \frac{d \vec{p}}{d t} = q \left( \vec{E} + \vec{v} \times \vec{B} \right) \]  \hspace{1cm} (42A)

The current 4-vector \( J^a \) is defined as:

\[ J^a = q v^a = q \left( \vec{v} c, \vec{v} n, \vec{v} \rho, \vec{v} s \right) \]  \hspace{1cm} (43A)

The current density 3-vector \( j \) is now defined, according to (42A), as:

\[ j^a = \left( \vec{v} c, \vec{v} n, \vec{v} \rho, \vec{v} s \right) \]  \hspace{1cm} (44A)

Then the force density 4-vector can be presented as:

\[ f^a = -F^{ab} j^b \]  \hspace{1cm} (46A)

which follows from substitution of (27A) and (44A) in (46A) and gives a similar result as equation (45A). Substituting (28A) in (46A) yields:

\[ f^a = \frac{1}{\mu_0} F^{ab} \partial_c F_{bc} = \partial_b T^{ab} \]  \hspace{1cm} (47A)

From (47A) it follows that in 3 dimensions the mechanical force \( \vec{F} \) acting on an arbitrary electromagnetic confinement equals:

\[ \vec{F} = \frac{1}{\mu_0} \int V \vec{T} - \int (n \cdot \vec{T}) d S \]  \hspace{1cm} (48A)

For that reason the energy-momentum tensor is often presented by:

\[ T^{ab} = \begin{vmatrix} w & -i \frac{\vec{S}}{c} \\ -i \frac{\vec{S}}{c} & -\frac{\vec{T}}{c} \end{vmatrix} \]  \hspace{1cm} (49A)

in which the tension sub-tensor \( \vec{T} \) describes the force density acting on the electromagnetic confinement. The momentum 4-vector in (33) is presented by:

\[ p^a = \frac{1}{c} \int V \vec{T}^{ab} d V \]  \hspace{1cm} (50A)

which equation equals (39) in the article. In this example a simplified energy-momentum tensor is chosen which describes the confinement of a monochromatic electromagnetic wave, presented in 8A, which
propagates along the x-axis between perfect reflecting mirrors, which counterbalance the radiation pressure due to the confinement. This balance is e.g. realized by putting an opposite electric charge on both perfect reflecting mirrors. When the energy density \( w_s = \frac{1}{2} E_s^2 \) of this static electric field equals the energy density \( w_D \) of the confined electromagnetic radiation, averaged over the period time, the system is in balance and under that restriction the Lorentz transformation of the energy-momentum tensor is allowed. The energy-momentum tensor equals:

\[
T^{ab} = \begin{pmatrix}
w_s + w_D & -i & S_x & 0 & 0 \\
-\frac{i}{c} & S_x & w_s - w_D & 0 & e_y E_x E_z \\
0 & 0 & T_{22} & 0 \\
0 & e_y E_x E_z & 0 & T_{33}
\end{pmatrix} \tag{51A}
\]

in which \( w_s \) is the static energy density due to the electric charge on both confining mirrors and equals:

\[
w_s = \frac{1}{2} e_0 E_x^2 \tag{52A}
\]

and \( w_D \) is the dynamic energy density of the confined electromagnetic radiation, propagating along the x-axis:

\[
w_D = \frac{1}{2} e_0 E_x^2 + \frac{1}{2\mu_0} B_y^2 \tag{53A}
\]

The term \( T_{22} \) equals:

\[
T_{22} = \frac{1}{\mu_0} B_y^2 - w_s - w_D \tag{54A}
\]

and the term \( T_{33} \) is equal to:

\[
T_{33} = e_0 E_x^2 - w_s - w_D \tag{55A}
\]

From (51A) it follows that the trace \( T^{ab} \) of the energy-momentum tensor is zero. The Lorentz transformation of (52A) is described by:

\[
T'^{ab} = L^d_a T^{ab} L^d_b \tag{56A}
\]

in which the tensor \( L^d_a \) equals:

\[
L^d_a = \begin{pmatrix}
\gamma & -\frac{i\gamma v}{c} & 0 & 0 \\
\frac{i\gamma v}{c} & \gamma & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix} \tag{57A}
\]

and the tensor \( L^d_b \) equals:

Substituting (51A), (57A) and (58A) in (56A) results for the term \( T_{10}' \) of the transformed energy-momentum tensor:

\[
T_{10}' = w_D' + w_S' - \gamma^2 \left( \frac{1}{c^2} \right) w_D + \frac{w_S}{\gamma^2} - \frac{2\nu S_x}{c^2} \tag{59A}
\]

and for the transformed term \( T_{10}' \):
The quantity $S_x$ describes the dynamic part of the Poynting vector and is indicated in the article as $S_{DX}$. Thus (60A) can be written as:

$$T^{\prime}_{10} = -\frac{i}{c} S'_x = -\frac{i\nu^2}{c} \left( 1 + \frac{\nu^2}{c^2} \right) S_x - 2\nu\nu_D$$

(60A)

The transformations (59A) and (61A) are presented in the article in equation (41). The 0-component of equation (47A) equals:

$$S'_{Dx} + S'_{Dy} = \gamma^2 \left( 1 + \frac{\nu^2}{c^2} \right) S_{Dx} + \frac{S_{Dx}}{\gamma^2} - 2\nu\nu_D$$

(61A)

Using (46A) to determine $f^a$ and substituting (33A) in (62A) results in the Poynting Theorem, better known as the continuity equation:

$$\vec{E} \cdot \vec{J} = -\frac{\partial}{\partial t} \vec{\nu} - \nabla \cdot \vec{S}$$

(63A)

In the absence of gravity and in perfect vacuum the left hand side of (62A) equals zero. In the article it will be demonstrated (equation 56) that the Schrödinger equation is a special notation for:

$$\partial_\alpha T^{\alpha\beta} = 0$$

(64A)

at non-relativistic velocities, so that the energy and the momentum are observed as separated quantities in which circumstance the Schrödinger equation controls the energy domain.
